Some implications and consequences of the expansion of the universe are examined. In Chapter 1 it is shown that this expansion creates grave difiiculties for the HoyleNarlikar theory of gravitation. Chapter 2 deals with perturbations of an expanding homogeneous and isotropic universe. The conclusion is reached that gelaxies cannot be formed as a result of the growth of perturbations that were initially small. The propagation and absorption of gravitational radiation is also investigated in this approximation. In Chapter 3 gravitational radiation in an expanding universe is examined by a method of asymptotic expansions. The 'peelingoff' behaviour and the asymptotic group are derived. Chapter 4 deals with the occurrence of singularities in cosmolo ical models. It is shown that a singularity is inevitable provided that certain vory general conditions are satisfied.

## INDRODUCSION

Tho idea that the univorno is expanding is of recont oricin. A12 the onsly cosmologios woro ossontinily stationary and evon Binstoin whoso theory of relativity is the basis for almost all modern dovelopments in cosmolosy, found it natural to succest a static modol of tho univorse. Hovevor there is a very erave difficulty associated with a static model such as minstoin's which is supnosed to heve existed for on infinito time. Por, if the stare had boon radiating onergy at thoir prosont rates for an infinite time, thoy would have neoded an infinite sup iy of enercy. Fupthor, tho flux of radiation now would be infinite. Alternatively, if they had only a limited supply of enerey, the whole universe would by now hove posehed thomel enuilibmium which is cemtainly not tho case. Mhis difficulty was noticed by Olbers who however wea not able to sugceat any solution. The diocov ry of tho recesgion of the nebulee by fiubbie 1 ed to the abandanmant of static models in fovour of ones which were expanding. Cloarly there aro soveral possibilities: the universe may heve oxpanded from a inighly donso state a finite time ogo (the so-c lled 'big-beng' model); another is thet tho present expansion eay have been proceded by a contraction which, in

Lis turn may have boon proceded by another exponolon (the 'bouncing' or oscilitating model), however, this modol awefore from the same difficultios over entropy as the static model: finnily it is poseible that tho oxptuneton moy have boon proceeding at much the samo mate for an infinite timo. It is then necossary $t 0$ pontviate somo fomm of continual croation of matter in order to prevont the expanslon from reducing the density to zoro. This Loade to the "oteady-state" model which aldhough expending prosents the samo appon rance at all timos. The eanly commologies naturally placed man at or moer the centre of the universe, but, oince the time of opernious we have been lomotod 60 a medium sined planet going round a medium sized stor somorhorg noat tho odTo of a fulwhy average aleany. We are now so humble thet we woulu not elaim to occupy any spectal ponition. Ttowever observations seen to indioato that ithin exporimental orror (which is faimly hich) Sazaxies h ve a mpatialiy isotroplc diotwibution arounc us. As we ame not alaiuing any Bpeckal pootbion the cistribution must be isotropic about ovory point. This implies thit the dibeributhon uat be apatialiy bomogonooue ts well as isotmopic. of course this homogenotuy man isotropy hoza onty on a zacco seule, loeally theme ame considepablo depaxtures from both.

Robertson and Walker have shown that the metric of a model that is spatially homosencous and isotropic may be written in tho form:

$$
\begin{gathered}
d s^{2}=d t^{2}-R^{2}(t)\left[\frac{d r^{2}}{1-k r^{2}}+r^{2}\left(d \theta^{2}+\sin ^{2} \theta d \phi^{2}\right)\right] \\
k=0 \text { or } \pm 1
\end{gathered}
$$

This form will be used extensively in the following chapters. In Chapter 1 it will be shown that the noyle-llarlikar theory of gravitation is incompatible with a metric of this form. In Chapter 2 perturbations of this form will be considered in a linearised approximation and, in Chapter 3 gravitational radiation will bo consaiered in a model which bonds asyntotically to this form.
certain of tho Robertson-ialkor models possess 'horizons'. There are two typos: particle horizons and event horizons. A particle horizon is said to exist when an observer's past light cone does not intersect tho world line of every particle in the universe (or extended world line in the case of a particle which has been created). in oxmplo of a moll with a particle horizon is the Einotoin-de witter model which has $K=0 \quad R=t \frac{2}{3}$. This 10 a 'bis-bang' model as indeed are all tho Robertson-malicer models that satisfy the Inctoin equations:

$$
R_{a b}-\frac{1}{2} g_{a b} R=T_{a b}
$$

and contain matter whose pressure is reater than minue onethird the density. An ovent howison extnte whon thowe are evonts that a given observer w 1.11 nover soe. The steedystate model $\left(K=0 \quad R=e^{t}\right) i s$ an oxample of one with an event homizon. Horizons will bo furthoz diocuosed in Ghapter 4 Whioh also doals with the ocournence of simgularitios of spacetimo and thoir connection with topolozy.

Bach chapter is solf-containod and has its own roforencos. The following notation is used throughout: space-time 16 taken to be a Riemannien monifo1d with motric tonsor $g_{i j}$. Ihis is taken to have signature -2 except in chapter 2 where, in ordor to facilitate comparison with previous worls, the aignature is 4 2。 Govaninnt aspeerontiation is indic bod by a. somi-colon. Units aro omployod in w-ich e, the speed of 1ight, and $K$, the gravitational constant, ocual one.

## ACKNOWLEDGEMENTS

I wish to thank my supervisor, Dr. D. W. Sciama
for his help and advice during my period of research. I would also like to thank Mr. B. Carter and Dr. G. F. R. Elis for many useful discussions. I am indebted to R. G. McLenaghan for the calculation of the Bianchi Identities in Chapter 3.
The research described in this thesis was
carried on while I held a Research Studentship from the D.S.I.R.

## CHAPTER 1

## The Hoyle-Ñarlikar Theory

of Gravitation

1. Introduction

The success of Maxwell's equations has led to
electrodynamics being normally formulated in terms of fields that have degrees of freedom independent of the particles in them. However, Gauss suggested that an action-at-a-distance theory in which the action travelled at a finite velocity might be possible. This idea was developed by Wheeler and Feynman $(1,2)$ who derived their theory from an action-principle that involved only direct interactions between pairs of particles. A feature of this theory was that the 'pseudo'-fields introduced are the half-retarded plus half-advanced fields claculated from the world-lines of the particles. However, Wheeler and Feynman, and, in a different way, Hosarth (3) were able to show that, provided certain cosmological conditions were satisfied, these fields could combine to give the observed field. Hoyle and Narlikar (4) extended the theory to general space-times and obtained similar theories for their 'C'-field (5) and for the gravitational field (6). It is with these theories that this chapter is concerned.

It will be shown that in an expanding universe the advanced fields are infinite, and the retarded fields finite. This is because, unlike electric charges, all masses have the same sign.
2. The Boundary Condition

Hoyle and Narlikar derive their theory from the action:

$$
A=\sum_{a \neq b} \iint G(a, b) d a d b
$$

where the integration is over the world-lines of particles $a, b \ldots$ In this expression $G$ is a Green function that satisfies the wave equation:

$$
G\left(x, x^{\prime}\right)_{i j j} g^{i j}+\frac{1}{6} R G\left(x, x^{\prime}\right)=\frac{\delta^{4}\left(x, x^{\prime}\right)}{\sqrt{-g}}
$$

where $g$ is the determinant of $g_{i j}$. Since the double sum in the action $A$ is symmetrical between all pairs of particles $a, b$, only that part of $G(a, b)$ that is symmetrical between $a$ and $b$ will contribute to the action i.e. the action can be written

$$
A=\sum_{a \neq b} \iint C^{*}(a, b) d a, d b
$$

where $C^{*}(a, b)=\frac{1}{2} G(a, b)+\frac{1}{2} G(b, a)$. Thus $G^{*}$ must be the time-symmetric Green function, and can be written: $G^{*}=\frac{1}{2} G_{\text {ret }}+\frac{i}{2} G_{a d v}$ where $G_{\text {ret }}$
and $C_{a d v}$ are the retarded and advanced Green functions. By requiring that the action be stationary under variations of the $g_{i j}$, Hoyle and Narlikar obtain the field-equations: $\left[\sum \sum \frac{1}{6} m^{(a)}(x) m^{(b)}(x)\right]\left(R_{i k}-\frac{1}{2} g_{i k} R\right)$

$$
\begin{gathered}
=-T_{i k}+\sum_{a \neq b} \frac{1}{3}\left[m^{(a)}\left(g_{i k} m_{j r}^{(b) r} m_{j i k}^{(b)}\right)+2\left(m_{; i}^{(a)} m_{; k}^{(b)}\right.\right. \\
\left.-\frac{1}{4} g_{i k} m^{(a) ; r} m_{; r}^{(b)}\right],
\end{gathered}
$$

where $m^{(a)}(x)=\int G^{*}(x, a) d a$. However, as a
consequence of the particular choice of Green function, the contraction of the field-equations is satisfied identically. There are thus only 9 equations for the 10 components of $g_{i j}$ and the system is indeterminate.

Hoyle and Narlikar therefore impose $\sum m^{(a)}=m_{0}=$ const., as the tenth equation. By then making the 'smooth-fluid' approximation, that is by putting $\sum_{a \neq b} m^{(a)} m^{(b)} \Omega m_{0}^{2}$, they obtain the Einstein field-equations:

$$
\frac{1}{6} m_{0}^{2}\left(R_{i k}-\frac{1}{2} R_{g_{i k}}\right)=-T_{i k}
$$

Thereis an important difference, however, between these field-equations in the direct-particle interaction theory and in the usual general theory of relativity. In the general theory of relativity, any metric that satisfies the
the field-equations is admissible, but in the direct-particle interaction theory only those solutions of the field-equations are admissible that satisfy the additional requirement:

$$
\begin{aligned}
& M_{0}(x)=\sum m^{(a)}(x)=\sum \int G^{*}(x, a) d a \\
& =\frac{1}{2} \sum \int G_{\text {ret }}(x, a) d a+\frac{1}{2} \sum \int_{a d v}(x, a) d a
\end{aligned}
$$

This requirement is highly restrictive; it will be shown that it is not satisfied for the cosmological solutions of the Einstein field-equations, and it appears that it cannot be satisfied for any models of the universe that either contain an infinite amount of matter or undergo infinite expansion.

The difficulty is similar to that occurring in Newtonian theory when it is recognized that the universe might be infinite.

The Newtonian potential $\phi$ obeys the equation:

$$
\square \phi=-k \rho \quad(\rho>0)
$$

where $\rho$ is the density.

In an infinite static universe, $\phi$ would be infinite, since the source always has the same sign. The difficulty was resolved when it was realized that the universe was expanding, since in an expanding universe the retarded solution of the above equation is finite by a sort of'red-shift' effect. The advanced solution will be infinite by a 'blue-shift' effect. This is unimportant in Newtonian theory, since one is free to choose the solution of the equation and so may ignore the infinite advanced solution and take simply the finite retarded solution.

Similarly in the direct-particle interaction theory the m-field satisfies the equation:

$$
\square m+\frac{1}{6} R_{m}=N \quad(N>0),
$$

where $N$ is the density of world-lines of particles. As in the Newtonian case, one may expect that the effect of the expansion of the universe will be to make the retarded solution finite and the advanced solution infinite. However, one is now not free to choose the finite retarded solution, for the equation is derived from a ärect-particle interaction actionprinciple symmetric between pairs of particles, and one must choose for $m$ half the sum of the retarded and advanced solutions. We would expect tais to be infinite, and this is shown to be so in the next section.
3. The Cosmological solutions

The Robertson-Walker cosmological metrics have the form

$$
d s^{2}=d t^{2}-R^{2}(t)\left[\frac{d r^{2}}{1-k r^{2}}+r^{2}\left(d \theta^{2}+\sin ^{2} \theta d \phi^{2}\right)\right]
$$

Since they are conformal flat, one can choose coordinates in which they become

$$
\begin{aligned}
d s^{2} & =\Omega^{2}\left[d \tau^{2}-d \rho^{2}+\rho^{2}\left(d \theta^{2}+\rho^{2} \sin ^{2} \theta d \phi^{2}\right)\right] \\
& =\Omega^{2} \eta_{a b} d x^{a} d x^{b}
\end{aligned}
$$

where $\eta a b$ is the flat-space metric tensor and

$$
\Omega=\Omega(\tau, \rho)=\frac{R(z)}{\sqrt{\left\{\left[i+\frac{1}{4} K(\tau+\rho)^{2}\right]\left[1+\frac{1}{4} K(\tau-\rho)^{2}\right]\right\}}}(7)
$$

For example, for the Einstein-de Sitter universe

$$
\begin{aligned}
& k=0, \quad R(t)=\left(\frac{t}{T}\right)^{\frac{2}{3}} \quad(0<t<\infty) \\
& \Omega=R=\left(\frac{\tau}{T}\right)^{2} \quad(0<\tau<\infty) \\
& r=\rho \quad\left(\tau=T^{\frac{2}{3}} t^{\frac{1}{3}}\right)
\end{aligned}
$$

For the steady-state (de Sitter) universe

$$
K=0, R(t)=\frac{t}{e \frac{t}{T}} \quad(-\infty<t<\infty)
$$

$$
\begin{aligned}
& \Omega=R=-\frac{T}{\tau} \quad(-\infty<\tau<0) \\
& r=\rho \quad\left(\tau=-T e^{\frac{-t}{T}}\right)
\end{aligned}
$$

The Green function $G^{*}(a, b)$ obeys the equation

$$
\square G^{*}(a, b)+\frac{1}{6} R G^{*}(a, b)=\frac{\delta^{4}(a, b)}{\sqrt{-g}}
$$

$$
\begin{aligned}
& \begin{aligned}
\frac{1}{\Omega^{4}} \frac{\partial}{\partial x^{a}}\left(\Omega^{2} \eta^{a b} \frac{\partial}{\partial x^{b}} G^{*}\right) & +\frac{\partial}{\partial x^{a}}\left(\eta^{a b} \frac{\partial}{\partial x^{b}} \Omega\right) \Omega^{-3} c^{*} \\
& =\Omega^{-4} \delta^{4}(a, b)
\end{aligned}
\end{aligned}
$$

If we let $G^{*}=\Omega^{-1} S$, then

$$
\Omega \frac{\partial}{\partial x^{a}}\left(\eta^{a b} \frac{\partial}{\partial x^{b}} S\right)=\delta^{4}(a, b)
$$

This is simply the flat-space Green function equation, and hence

$$
\left.\begin{array}{rl}
G^{*}\left(\tau_{1}, 0 ; \tau_{2} \rho\right) & =\frac{\Omega^{-1}\left(\tau_{1}\right)}{8 \pi}\left[\frac{\delta\left(\rho-\tau_{2}+\tau_{1}\right)}{\Omega\left(\tau_{2}\right) \rho}\right. \\
& -\delta\left(\rho+\tau_{2}-\tau_{1}\right) \\
\Omega\left(\tau_{2}\right) \rho
\end{array}\right] .
$$

The' $m$ '- field is given by

$$
m\left(\tau_{2}\right)=\int a^{*} N J-g d x^{4}=\frac{1}{2}\left(m_{\text {ret. }}+m_{\text {adv. }}\right) \text {. }
$$

For universes without creation (egg. the Einstein-de Sitter universe), $N=R^{-3} n ; \quad n=$ cont. For
universes with creation (steady state) $N=\Omega, \Omega=$ const.

$$
m_{a \partial v}\left(\tau_{1}\right)=\Omega^{-1}\left(\tau_{1}\right) \int \frac{N \Omega^{3}\left(\tau_{2}\right) 4 \pi r^{2} d r}{4 \pi r}
$$

where the integration is over the future light cone. This will normally be infinite in an expanding universe, e:g. in the Einstein-de sitter universe.

$$
\begin{aligned}
M_{a . d}\left(\tau_{1}\right) & =\left(\frac{\tau_{1}}{T}\right)^{-2} \int_{\tau_{1}}^{\infty} n\left(\tau_{2}-\tau_{1}\right) d \tau_{2} \\
& =\infty
\end{aligned}
$$

In the steady-state universe

$$
n_{a d v_{1}}\left(\tau_{1}\right)=\left(\frac{-T}{\tau_{1}}\right)^{-1} \int_{\tau_{1}}^{0}-n\left(\frac{T}{\tau_{2}}\right)^{3}\left(\tau_{2}-\tau_{1}\right) d \tau_{2} .
$$

$$
=\infty
$$

By contrast, on the other hand, we have

$$
m_{\text {ret }}\left(\tau_{1}\right)=\Omega^{-1}\left(\tau_{i}\right) \int \frac{N \Omega^{3}}{4 \pi r} 4 \pi r^{2} d r
$$

where the integration is over the past light cone. This will
normally be finite, e.g. in the Jinstein-de sitter universe

$$
m_{\text {ret. }}\left(\tilde{\tau}_{1}\right)=\left(\frac{\tau_{1}}{T}\right)^{-2} \int_{0}^{\tau_{i}}-n\left(\tau_{2}-\tau_{1}\right) d \tau_{2}=\frac{1}{2} n T^{2}
$$

While in the steady-state universe

$$
\begin{gathered}
m_{\text {ret }}\left(\tau_{1}\right)=\left(\frac{-T}{\tau_{1}}\right)^{-1} \int_{-\infty}^{\tau} n\left(\frac{T}{\tau_{2}}\right)^{3}\left(\tau_{2}-\tau_{1}\right) d \tau_{2} \\
=\frac{1}{2} n T^{2}
\end{gathered}
$$

Thus it can be seen that the solution $m=$ const. of the equation

$$
\square m+\frac{1}{6} R m=N
$$

is not, in a cosmological metric, the half-advanced plus half-retarded solution since this would be infinite. In fact, in the case of the Einstein-de Sitter and steady-state metrics, it is the pure retarded solution.

## 4. The 'C'-rield

Hoyle and Narlikar derive their direct-particle interaction theory of the 'c'-field from the action

$$
A=\sum_{a \neq b} \sum_{a} \int \hat{\vec{G}}(a, b): i_{a_{b}^{k}} d a^{i} d b^{k}
$$

Where the suffixes $a, b$ refer to differentiation of $\hat{G}(a, b)$ on the world-lines of $a, b$ respectively. $\hat{C}_{i}$ is a Green function obeying the equation

$$
\Delta \hat{q}\left(x, x^{\prime}\right)=\frac{\delta^{4}\left(x, x^{\prime}\right)}{\sqrt{-g}} .
$$

we define the 'C'-field by

$$
C(x)=\sum^{C} \int \hat{G}(x, a)_{; i a} d a^{i},
$$

and the matter-current $J^{k}$ by

Then

$$
J^{k}(y)=\sum \int_{0} \delta^{4}(y, b) d b^{k}
$$

$$
C(x)=\int \hat{G}(x, y) J^{k}(y)_{j k} \sqrt{ }-g d x^{4}
$$

$$
\square C=J^{k} ; K
$$

We thus see that the sources of the 'C'-field are the places where matter is created or destroyed.
is in the case of the ' $m$ '-field, the Green function must be time-symmetric, that is

Hoyle and Narlikar claim that if the action of the 'C'-field is included alone with the action of the 'm '-field, a universe will be obtained that approximates to the steadystate universe on a large scale although there may be local irregularities. In this universe, the value of $C$ will be finite and its gradient time-like and of unit magnitude.

Given this universe, we may check it for consistency by claculating the advanced and retarded 'C'-fields and finding if their sum is finite. We shall not do this directly but will show that the advanced field is infinite while the retarjed field is finite.

Consider a region in space-time bounded by a threedimensional space-like hypersurface $D$ at the present time, and the past light cone $\sum$ of some point $P$ to the future of 1

$$
\begin{array}{r}
\int_{V} \square C J-g d x^{4}=\int_{\Sigma+D} \frac{\partial C}{\partial n} d S \\
=\int J_{; k}^{k} \sqrt{ }-g d x^{4}
\end{array}
$$

Let the advanced field produced by sources within $V$ be $C^{\prime}$.

$$
\int_{V} J^{k} ; k J-g d x^{4}=\int_{D} \frac{\partial C^{\prime}}{\partial n} d S
$$

But $j_{j k}^{k}$ is the rate of creation of matter $=n$ (const.) in the steady-state universe, and hence

$$
\int_{i} \frac{\partial C^{\prime}}{\partial n} d S=n V
$$

is the point $P$ is taken further into the future, the volume of the region $V$ tends to infinity. However, the area of the hypersurface $D$ tends to a finite limit owing to horizon effects. Therefore the gradient $\frac{\partial C}{\partial n}$ must be infinite. A similar calculation shows the gradient of the retarded field to be finite. Their sums cannot therefore give the field of unit gradient required by the Hoyle-Narlikar theory. It is worth noting that this result was obtained without assumptions of a smooth distribution of matter or of conformalifatness.
5. Conclusion

It is one of the weaknesses of the Einstein theory of relativity that although it furnishes field equations it does not provide boundary conditions for them. Thus it does not give a unique model for the universe but allows a whole series of models. Clearly a theory that provided boundary conaitions and thus restricted the possible solutions would be very attractive. The Hoyle-Narlikar theory does just that(the requirement that $m=\frac{1}{2} m_{\text {ret }}+\frac{1}{2} m_{a \partial v}$. is equivalent to a boundary condition). Unfortunately, as we have seen above, this condition excludes those rodels that seem to correspond to the actual universe, namely the Robertson-Walker models.

The calculations given above have considered the universe as being filled with a uniform distribution of matter. Whis is legitimate if we are able to make the 'smooth-fluid' approximation to obtain the Binstein equations. Alternatively if this approximation is invalid, it cannot be said that the theory yields the Einstein equations.

It might possibly be that local irresularities could make $m_{a d v}$ finite, but this has certainly not been demonstrated and seems unlikely in view of the fact that, in the HoyleNarlikar direct-particle interaction theory of their 'C'-field,

which is derived from a very similar action-principle, it can be shown without assuming a smooth distribution that the advanced 'C' field will be infinite in an expanding universe with creation.

The reason that it is possible to formulate a directparticle interaction theory of electrodynamics that does not encounter this difficulty of having the advanced solution infinite is that in electrodynamics there are equal numbers of sources of positive and negative sign. Their fields can cancel each other out and the total field can be zero apart from local irregularities. This suggest that a possible way to save the Hoyle-Narlikar theory would be to allow masses of both positive and negative sign. The action would be

$$
A=\sum_{a \neq b} q_{a} q_{b} \iint G^{*}(a, b) d a d b \quad\left(q_{a,} q_{b}= \pm 1\right.
$$

where $q a, q 6$ are gravitational charges analogous to electric charms. Particles of positive $q$ in a positive 'm'-field and particles of negative $q$ in a negative ' $m$ ' field would have the normal gravitational properties, that is, they would have positive gravitational and inertial masses.

A particle of negative $q$ in a positive 'm 'rield would still follow a geodesic. Therefore it would be attracted by a particle of positive $q$. Its own gravitational effect however would be to repel all other particles. Mhus it would have the properiies of the negative mass described by Bondi (8) that is, negative gravitational mass and negative inertial mass.

Since there does not seem to be any matter having these oroperties in our region of space (where $m \Omega$ const. $>0$ ) there must clearly be separation on a very large scale. It would not be possible to identify particles of negative $q$ with antimatter, since it is known that antimatter has positive inertial mass. Hwever, the introduction of negative masses would probably raise more difficulties than it wuld solve.

## CHAPTER 2

## PERTURBATIONS

## 1. Introduction

Perturbations of a spatially isotropic and homogeneous expanding universe have been investigated in a Newtonian approximation by Bonnor (1) and relativistically by Lifshitz (2), Liftshitz and Khalatnikov (3) and Irvine ${ }^{(4)}$. Their method was to consider small variations of the metric tensor. This has the disadvantage that the metric tensor is not a physically significant quantity, since one cannot directly measure it, but only its second derivatives. It is thus not obvious what the physical interpretation of a given perturbation of the metric is. Indeed it need have no physical significance at all, but merely correspond to a coordinate transformation. Instead it seems preferable to deal in terms of perturbations of the physically significant quantity, the curvature.

## 2. Notation

Space-time is represented as a four-dimensional Riemannian space with metric tensor $g_{a b}$ of signature +2 . Covariant differentiation in this space is indicated by a semi-colon. Square brackets around indices indicate antisymmetrisation and round brackets symmetrisation. The conventions for the Riemann and Ricci tensors are:-

$$
\begin{aligned}
& V_{a ;}[b c]=2 R_{a, c b}^{p} V_{p} . \\
& R_{a b}=R_{0}^{p} b_{p}
\end{aligned}
$$

Mabed is the alternating tensor.
Units are such that $k$ the gravitational constant and $c$, the speed of
light are one.

UNIVERSITY
LIBRARY
CAMBRIDGE

## 3. The Field Equations

We assume the Einstein equations:

$$
R_{a b}-\frac{1}{2} g_{a b} R=-T_{a b}
$$

where $\mathrm{T}_{\mathrm{ab}}$ is the energy momentum tensor of matter. We will assume that the matter consists of a perfect fluid. Then,

$$
T_{a b}=\mu u_{a} u_{b}+h h_{a b}
$$

where $U_{a}$ is the velcity of the fluid, $U_{a} U^{a}=-1$ :

$$
\begin{aligned}
& \mu \text { is the density. } \\
& h \text { is the pressure. } \\
& h_{a b}=g_{a b}+u_{a} u_{b} \quad \text { is the projection operator }
\end{aligned}
$$

into the hyperplane orthogonal to $U_{a}$ :

$$
h_{a b} u^{b}=0 \text {. }
$$

We decompose the gradient of the velocity vector $U_{a}$ as

$$
u_{a ; b}=\omega_{a b}+\sigma_{a b}+\frac{1}{3} h_{a b} \theta-\dot{u}_{a} u_{b}
$$

where

$$
\begin{array}{ll}
\dot{u}_{a}=u_{a ; b} u^{b} & \text { is the acceleration, } \\
\theta=u_{a} ; a & \text { is the expansion, } \\
\sigma_{a b}=u_{\langle c ; d)} h_{d}^{c} h_{b}^{d}-\frac{1}{3} h_{a b} \theta & \text { is the shear, } \\
\omega_{a b}=u_{[c ; d]}^{c} h_{a}^{c} h_{b}^{d} & \text { is the rotation of the }
\end{array}
$$

flow lines $U_{a}$. We define the rotation vector $\omega_{a}$ as

$$
\omega_{a}=\frac{1}{2} \eta_{a b c d} \omega^{c d} u^{b} \text {. }
$$

We may decompose the Riemann tensor $\mathrm{R}_{\text {abcd }}$ into the Ricci tensor
$R_{a b}$ and the leyl tensor $C_{a b c d}$ :
$R_{a b c t}=C_{a b c d}-g_{a[d} R_{c] b}-g_{b[c} R_{d] a}-R_{/ 3} g_{a[c} g_{d] b}$,
$\left.C_{a b c d}=C_{[a b][c d]}\right]$,
$C^{a}, b c a=0=C_{a[b c d]}$.
$C_{\text {abed }}$ is that part of the curvature that is not determined locally by the matter. It may thus be taken as representing the free gravitational field (Jordan, Ehlers and Wundt ${ }^{(5)}$ ). We may decompose it into its "electric" and "magnetic" components.

$$
\begin{aligned}
E_{a b}= & -C_{0 b p q} u^{p} u^{q}, \\
H_{a b}= & -\frac{1}{2} C_{a}^{p q r} \eta_{q r b s} u_{p} u^{s}, \\
C_{a b}^{c d}= & 8 u_{[a} E_{b]}^{[c} u^{d]}-4 \delta_{[a}^{[c} E_{b]}^{d]}, \\
& -2 \eta_{a b c d} u^{p} H^{q[c} u^{d]}-2 \eta^{c d r s} u_{r} H_{s[a} u_{b]}, \\
E_{a b}= & E_{(a b)}, \quad H_{a b}=H_{(a b)},
\end{aligned}
$$

$$
E_{a}^{a}=H_{a}^{a}=0
$$

$$
E_{a b} u^{b}=H_{a b} u^{b}=0
$$

$\mathbb{E}_{a b}$ and $H_{a b}$ each have five independent components.
We regard the Bianchi identities,

$$
R_{a b}[c d j e]=0
$$

as field equations for the free gravitational field.
Then

$$
\left.C_{a b c d} ; d=-R_{c[b ; a]+\frac{1}{6}} g_{c}\left[b R_{; a}\right] \quad \text { (Kundt and Tramper, }{ }^{(6)}\right)
$$

Using the decompositions given above, we may write these in a form analogous to the Maxwell equations.
$h_{a}^{b} E_{b c ; d} h^{c d}+3 H_{a b} \omega^{b}-\eta_{a b c d} u^{b} \sigma^{c} e H^{d e}=\frac{1}{3} h_{a}^{b} \mu_{;} b$,
$h_{a}^{b} H_{b c ; d} h^{c d}-3 E_{a b} \omega^{b}-\eta_{a b c d} u^{b} \sigma^{c} e E^{d e}=(\mu+h) \omega_{a}$,
$\left.1 \dot{E}_{a b}+h_{(a}{ }^{f} \eta b\right) c d e u^{c} H_{f}^{d ; e}+E_{a b} \theta-E^{c}\left(a \omega_{b) c}\right.$
$-E_{\left(a \sigma_{b) c}\right.}^{c}-\eta_{a c d e} \eta_{b p q r} u^{c} u^{p} \sigma^{d q} E^{e r}$
$+2 H_{a}^{d} \eta_{b c d e} u^{c} \dot{u}^{e}=-\frac{1}{2}(\mu+h) \sigma_{a b}$,
$\left.1 \dot{H}_{a b}-h_{(a}^{f} \eta b\right) c d e u^{c} E_{f}^{d ; e}+H_{\alpha b} \theta-H_{(a}^{c} \omega_{b) c}$

- $H^{c}{ }_{(a} \sigma_{b) c}-\eta_{a s d e} \eta_{b p q r} u^{c} u^{p} \sigma^{d q} H^{e r}$
$+2 H^{d}$ a $\eta_{\text {bade }} u^{c} \dot{u}^{e}=0$
where $\perp$ indicates projection by $h_{a b}$ orthogonal to $U_{a}$. (c.f. Trimper, ${ }^{(7)}$ ).

The contracted Bianchi identities give,

$$
\begin{align*}
& \left(R_{a b}-\frac{1}{2} g_{a b} R\right)^{; b}=-T_{a b} ; b=0 \\
& \dot{\mu}+(\mu+h) \theta=0  \tag{5}\\
& (\mu+h) \dot{u}_{a}+\gamma_{2} ; b h_{a}^{b}=0 \tag{6}
\end{align*}
$$

The definition of the Riemann tensor is,

$$
u_{a ;[b c]}=2 R_{a p b c} u^{p}
$$

Using the decompositions as above we may obtain what may be regarded as "equations of motion".

$$
\begin{align*}
& \dot{\theta}=2 \omega^{2}-2 \theta^{2}-\frac{1}{3} \theta^{2}+\dot{u}_{a} a^{\beta}-\frac{1}{2}(\mu+3 h),  \tag{7}\\
& \left.1 \dot{\omega}_{a b}=-\frac{2}{3} \omega_{a b} \theta+2 \sigma_{c[a} \omega_{b}\right]^{c}+\dot{u}_{[p ; q]} h_{a}^{p} h_{b}^{q},  \tag{8}\\
& \mathcal{L}_{a b}=E_{a b}-\omega_{a c} \omega^{c} \omega_{b}-\sigma_{a c} \sigma_{b}^{c}-\frac{2}{3} \sigma_{a b} \theta \\
& -\frac{1}{3} h_{a b}\left(2 \omega^{2}-2 \sigma^{2}+\dot{u}_{c}{ }^{c}\right)+\dot{u}_{a} \dot{u}_{b} \\
& +\dot{u}(p ; q) h_{a}^{p} h_{b}^{q}, \tag{9}
\end{align*}
$$

where

$$
2 \omega^{2}=\omega a b \omega^{a b}
$$

$2 \sigma^{2}=\sigma_{a b} \sigma^{a b}$
We also obtain what may be regarded as equations of constraint.

$$
\begin{equation*}
\theta ; b h_{a}^{b}=\frac{3}{2}\left[\left(\omega_{c}^{b} ; b+\sigma^{b} c ; b\right) h_{a}^{c}-\dot{u}^{b}\left(\omega_{a b}+\sigma_{a b}\right)\right] \tag{10}
\end{equation*}
$$

(a) $a^{; a}=2 \omega \dot{u}^{a}$,
$H_{a b}=-h^{f}\left(a \eta_{b}\right) c d e u^{c}\left[\omega_{f}^{d ; e}+\sigma_{f}^{d ; e}\right]$.

We consider perturbations of a universe that in the undisturbed state in conformally flat, that is

$$
C_{a b c d}=0
$$

By equations $(1)-(3)$, this implies,

$$
\begin{aligned}
& \sigma_{a b}=(a) a b=0 \\
& h_{a}^{b} \mu ; b=0=\theta ; b h_{a}^{b}
\end{aligned}
$$

If we assume an equation of state of the form, $\nsim=\{(\mu)$,㚣en by (6), (10), $\quad \hat{\eta}_{2} ; h^{b}{ }_{a}=0=\dot{u}_{a}$

This implies that the universe is spatially homogeneous and isotropic since there is no direction defined in the 3 -space orthogonal to $U_{a}$.

In this universe we consider small perturbations of the motion of the fluid and of the Weyl tensor. We neglect products of small quantities and perform derivatives with respect to the undisturbed metric. Since all the quantities we are interested in with the exception of the scalars, $\mu, \not, \not, \theta$ have unperturbed value zero, we avoid perturbations that merely represent coordinate transformation and have no physical significance.

To the first order the equations (1) - (4) and (7) - (9) are

$$
\begin{equation*}
E_{a b} b^{b}=\frac{1}{3} h_{a}^{b} \mu ; b \text {, } \tag{13}
\end{equation*}
$$

$$
\begin{equation*}
H_{a b} ; b=(\mu+h) \omega_{a} \tag{14}
\end{equation*}
$$

$$
\begin{equation*}
E_{a b}+E_{a b} \theta+h^{f}(a \eta b) c d e u^{c} H_{f}^{d ; e}=-\frac{1}{2}(\mu+h) \sigma_{a b} \tag{15}
\end{equation*}
$$

$$
\begin{equation*}
\dot{H}_{a b}+H_{a b} \theta-h^{f}(a \eta b) c d e u^{c} E_{f}^{d j e}=0 \text {, } \tag{16}
\end{equation*}
$$

$$
\begin{equation*}
\dot{\theta}=-\frac{1}{3} \theta^{2}+\dot{u}_{a} ; a-\frac{1}{2}(\mu+3 k) \tag{17}
\end{equation*}
$$

$$
\begin{equation*}
\dot{\omega}_{a b}=-\frac{2}{3} \omega_{a b} \theta+\dot{u}_{[p ; q]} h_{a}^{p} h_{b}^{q}, \tag{18}
\end{equation*}
$$

$$
\begin{equation*}
\dot{\sigma}_{a b}=E_{a b}-\frac{2}{3} \sigma_{a b} \theta-\frac{1}{3} h_{a b} \dot{u}_{c} ; c+\dot{u}_{(p ; q)} h_{a}^{p} h_{b}^{q} . \tag{19}
\end{equation*}
$$

From these we see that perturbations of rotation or of $\mathbb{E}_{a b}$ or $H_{a b}$ do not produce perturbations of the expansion or the density. Nor do perturbations of $E_{a b}$ and $H_{a b}$ produce rotational perturbations.
4. The Undisturbed Metric

Since in the unperturbed state the rotation and acceleration are zero, $U_{a}$ must be hypersurface orthogonal.

$$
u_{a}=\tau_{; a},
$$

where $\tau$ measures the proper time along the world lines. As the surfaces $\tau=$ constant are homogeneous and isotropic they must be 3-surfaces of constant curvature. Therefore the metric can be written,

$$
d s^{2}=-d \tau^{2}+\Omega^{2} d \gamma^{2}
$$

where

$$
\begin{aligned}
& \Omega=\Omega \Omega(\gamma), \\
& d \gamma^{2} \text { is the line element of a space of } \\
& \text { zero or unit positive or negative curvature. }
\end{aligned}
$$

We define $t$ by,

$$
\frac{d t}{d \tau}=\frac{1}{\Omega}
$$

then

$$
d s^{2}=\Omega^{2}\left(-\alpha t^{2}+d \gamma^{2}\right)
$$

In this metric,

$$
u_{a}=(-5,0,0,0)
$$

$$
\therefore \quad \theta=\frac{3 \dot{\Omega}}{\Omega}=\frac{3 \Omega^{\prime}}{\Omega^{2}}
$$

(prime denotes differentiation with respect to $t$ )

Then, by (5), (7)

$$
\begin{align*}
& \dot{\mu}=-(\mu+h) \frac{3 \dot{\Omega}}{\Omega}  \tag{20}\\
& 3 \frac{\ddot{\Omega}}{\Omega}=-\frac{1}{2}(\mu+3 h) \tag{21}
\end{align*}
$$

If we know the relation between $\mu$ and $\nprec$, we may determine $\Omega$.
We will consider the two extreme cases, $\uparrow=0$ (dust) and $h=\frac{\mu}{3}$ (radiation). Any physical situation should lie between these. For $h=0$
By (20), $\mu=\frac{M}{S l^{3}} \quad M=$ const.
$\therefore \quad \frac{3}{M} \frac{\ddot{\varrho}}{\Omega}-\frac{1}{2 \Omega^{3}}=0$
$\therefore \quad \frac{3}{M} \dot{\Omega}^{2}-\frac{1}{\Omega}=E \quad, \quad E=$ const.
(a) For E 0 ,

$$
\Omega=\frac{1}{2 E}\left(\cosh \sqrt{\frac{E M}{3}} t-1\right), \quad r=\frac{1}{2 E}\left(\sqrt{\frac{3}{E M}} \sinh \sqrt{\frac{E M}{3}} t-t\right) ;
$$

(b) For $\mathbb{E}=0$,

$$
\Omega=\frac{M}{12} t^{2},
$$

$$
\tau=\frac{M}{36} t^{3}
$$

(c) For E O,
$\Omega=\frac{-1}{2 E}\left(1-\cos \sqrt{\frac{-E M}{3}} t\right), \quad \tau=\frac{-1}{2 E}\left(t-\sqrt{\frac{3}{-E M}} \sin \sqrt{\frac{-E M}{3}} t\right)$.
E represents the energy (kinetic + potential) per unit mass. If it is non-negative the universe will expand indefinitely, otherwise it will eventually contract again.

By the Gauss Codazzi equations *R, the curvature of the
hypersurface $\tau=$ constr.; is

$$
\begin{aligned}
* R & =2\left(-\frac{1}{3} \theta^{2}+\mu\right) \\
& =-\frac{2 E M}{\Omega^{2}}
\end{aligned}
$$

If $E>0$

$$
* R=-\frac{6}{\Omega^{2}} \quad, \quad M=\frac{3}{E}
$$

$E=0, * F=0 ;$
$E<0, \quad * R=\frac{6}{\Gamma^{2}}, \quad M=\frac{-3}{E}$
For $N=\mu / 5$

$$
\begin{array}{ll}
\dot{\mu}=-4 \frac{\dot{\Omega}}{\Omega}, \\
\frac{3 \ddot{\Omega}}{\Omega}=-\mu, \\
\mu=\frac{M}{\Omega^{4}}, & \therefore \frac{3 \dot{\Omega}^{2}}{M}-\frac{1}{\Omega^{2}}=E
\end{array}
$$

(a) For E $>0$,
$\Omega=\frac{1}{E} \sinh t, \quad \tau=\frac{1}{E}(\cosh t-1), \quad * R=-\frac{G}{S \Omega^{2}} ;$
(b) For $E=0$,
$\Omega=t, \quad \tau=\frac{1}{2} t^{2}$,

$$
{ }^{*} K=0 ;
$$

(c) For E O,
$\Omega=-\frac{1}{E} \sin t$,
$\tau=\frac{1}{E}(\cos t-1)$,
${ }^{*} R=\frac{6}{\Omega^{2}}$.
5. Rotational Perturbations
By (6)

$$
\dot{u}[c ; d] h_{a}^{c} h_{b}^{d}=-\frac{\omega_{a b} \dot{h}}{\mu+h}
$$

$$
\therefore \quad \dot{\omega}_{a b}=-\omega_{a b}\left(\frac{2}{3} \theta+\frac{\dot{p}^{\mu}}{\mu+\mu}\right)
$$

For $h=0$,

$$
\omega=\frac{\omega}{52^{2}}
$$

For $\quad\left\{=\frac{\mu}{3}\right.$,

$$
\begin{aligned}
\dot{\omega} & =-\omega\left(\frac{2}{3} \theta+\frac{1}{4} \frac{\dot{\mu}}{\mu}\right) \\
& =-\frac{1}{3} \omega \theta
\end{aligned}
$$

$$
\therefore \quad \omega \quad=\frac{\omega_{0}}{S}
$$

Thus rotation dies away as the universe expands. This is in fact a statement of the conservation of angular momentum in an expanding universe

## 6. Perturbations of Density

For $f_{2}=0$ we have the equations,

$$
\begin{aligned}
& \dot{\mu}=-\mu \theta \\
& \dot{\theta}=-\frac{1}{3} \theta^{2}-\frac{1}{2} \mu
\end{aligned}
$$

These involve no spatial derivatives. Thus the behaviour of one region is unaffected by the behaviour of another. Perturbations will consist in some regions having slightly higher or lower values of E than the average. If the unjverse as white has a value of E greater than zero, a small perturbation will till have E greater than zero and will continue to expand. It will not contract to
form a galaxy. If the universe has a value of $E$ less than zero, a small perturbation can contract. However it will only begin contracting at a time $\delta \tau$ earlier than the whole universe begins contracting, where

$$
\frac{\delta_{0} \tau}{\tau:}=\frac{\delta E}{E_{0}}
$$

$\tau_{0}$ is the time at which the whole universe begins contracting. There is only any real instability when $E=0$. This case is of measure zero relative to all the possible values E can have. However this cannot really be used as an arguement to dismiss it as there might be some reason why the universe should have $\mathrm{I}=0$ 。 For a region with energy $-\delta$, in a universe with $\mathrm{E}=0$

$$
\begin{aligned}
& \Omega=\frac{1}{4 \delta E}\left(t^{2}-\frac{t^{4}}{12}+\cdots\right) \\
& \tau=\frac{1}{12 S E}\left(t^{3}-\frac{t^{5}}{20}+\cdots\right) \\
& \mu=\frac{3}{\delta E S \Omega^{3}}=\frac{4}{3} \tau^{-2}\left(1+\frac{(\delta E)^{2 / 3}}{2 \sqrt{3}} \tau^{2 / 3}+\cdots\right)
\end{aligned}
$$

For $E=0, \mu=\frac{4}{3} \tau^{-2}$
Thus the perturbation grows only as $\tau^{2 / 3}$. This is not fast enough to produce galaxies from statistical fluctuations even if these could occur. However, since an evolutionary universe has a particle horizon (Rindler ${ }^{(8)}$, Penrose ${ }^{(9)}$ ) different parts do not communicate in the early stages. This makes it even more difficult for statistical fluctuations to occur over a reg:'n until light had time to cross the region.

For $\quad h=\mu / 3$

$$
\begin{aligned}
& \dot{\mu}=-\frac{4}{3} \mu \theta \\
& \dot{\theta}=-\frac{1}{3} \theta^{2}-\mu+\dot{u}_{a} ; a \\
& \dot{u}_{a}=-\frac{h^{b} a \mu ; b}{4 \mu}
\end{aligned}
$$

As before, a perturbation cannot contract unless it has a negative value of E. The action of the pressure forces make it still more difficult for it to contract. Eliminating $\theta$,

$$
\begin{aligned}
& \mu \ddot{\mu}^{-}-\frac{5}{4} \dot{\mu}^{2}-\frac{4}{3} \mu^{3}+\frac{4}{3} \mu^{2} \dot{u}_{a^{\prime a}}=0 \\
& \dot{u}_{a} ; a=\dot{u}_{a ; b} h^{a b}+\dot{u}_{a} \dot{u}^{a} \\
&=-\frac{1}{4} \frac{h^{a c}\left(h_{a}^{b} \mu ; b\right) ; c}{\mu}
\end{aligned}
$$

to our approximation。
$h^{a c} \nabla_{c} h_{a}^{b} \nabla_{b}$ is the Laplacian in the hypersurface $r=$ constant. We represent the perturbation as a sum of eigenfunctions $s(n)$ of this operator, where,

$$
\begin{aligned}
& S^{(n)} ; c u^{c}=0 \\
& h^{a c}\left(h_{a}^{b} S^{(n)} ; b\right) ; c=-\frac{n^{2}}{\Omega^{2}} S^{(n)}
\end{aligned}
$$

These eigenfunctions will be hyperspherical and pseudohyperspherical harmonics in cases (c) and (a) respectively anc plane waves in case (b). In case (c) $n$ will take only discrete . lues but in (a) and (b) it will take all positive values.

$$
\mu=\mu_{0}\left[1+\sum_{n} B^{(n)} S^{(n)}\right]
$$

where $\mu_{0}$ is the undisturbed density.

$$
\therefore \ddot{B}^{(n)} \mu_{0}-\frac{1}{2} \dot{B}^{(n)} \dot{\mu}_{0}-B^{(n)}\left[\frac{4}{3} \mu_{0}^{2}-\frac{n^{2}}{3 \Omega^{2}} \mu_{0}\right]=0
$$

As long as $\mu_{0}>\frac{n^{2}}{4 \Omega^{2}}, B^{(n)}$ will grow.
For $\mu_{0} \gg \frac{n^{2}}{4 \Omega^{2}}$

$$
B^{(r)} \bumpeq C \tau+D \tau^{-1}
$$

These perturbations grow for as long as light has not had time to travel a significant distance compared to the scale of the perturbation ( $\sim \frac{\Omega}{n}$ ). Until that time pressure forces cannot act to even out perturbations.

$$
\text { When } \frac{n^{2}}{\Omega}>\mu_{0}, \quad B^{\prime \prime}(n)+B^{\prime}(n) \frac{\Omega^{\prime}}{\Omega}+\frac{n^{2}}{3} B^{(n)}=0 \text {, }
$$

$$
\therefore \quad B^{(n)}=C S \Omega^{-\frac{1}{2}} e^{i \frac{n}{\sqrt{3}} t}
$$

We obtain sound waves whose amplitude decreases with time. These results confirm those obtained by Lifshitz and Khalatnikov (3). From the forgoing we see that galaxies cannot form as the result of the growth of small perturbations. We may speect that other nongravitational force will have an effect smaller than pressure equal
to one third of the density and so will not cause relative perturbations to grow faster than $\tau$. To account for galaxies in an evolutionary universe we must assume there were finite, non-statistical, initial inhomogeneities.
7. The Steady-state Universe

To obtain the steady-state universe we must add extra terms to the energy-momentum tensor. Hoyle and Narlikar (10) use,

$$
\begin{equation*}
T_{a b}=\mu u_{a} u_{b}+12 h_{a b}-C_{a} C_{b}+1 / 2 g_{0 b} C_{d} C^{d} \tag{20}
\end{equation*}
$$

where,

$$
\begin{aligned}
& C_{a}=C ; a, \\
& C_{; a}^{a}=-j a ; a \\
& j_{a}=(\mu+h) U_{a}
\end{aligned}
$$

Since $T_{a b}{ }^{b b}=0$

$$
\begin{align*}
& \mu+(\mu+h) \theta+u^{a} C_{a} C_{b} ; b=0  \tag{21}\\
& (\mu+h) \dot{u}_{a}+p_{; b} h_{a}^{b}-h_{a}^{b} C_{b} C_{d^{i d}}=0 . \tag{22}
\end{align*}
$$

There is a difficulty here, if we require that the "C" field
should not produce acceleration or, in other words, that the matter created should have the same velocity as the matter already in existence. We must tiện have

$$
\begin{equation*}
h^{b} C_{b}=0 \tag{23}
\end{equation*}
$$

However since C is a scalar, this implies that the rotation of the medium is zero. On the other hand if (23) does not hold, the equations are indeterminate (c.I. Raychaudhuri and Bannerjee(11)). In order to have a determinate set of equations we will adopt (23) but drop the requirement that $C_{a}$ is the gradient of a scalar. The condition (23) is not very satisfactory but it is difficult to think of one more satisfactory. Hoyle and Narlikar ${ }^{(12)}$ seek to avoid this difficulty by taking a particle rather than a fluid picture. However this has a serious drawback since it leads to infinite fields (Hawking ${ }^{(13)}$ ). From (17),

$$
C_{a}=-u_{a}\left[1-\frac{\dot{i}}{\dot{\mu}+h+(\mu+h) \theta}\right]
$$

$$
\begin{aligned}
& \therefore C_{a}:^{a}=-(\dot{\mu}+i)-(\mu+12) \theta \text {, } \\
& =-\theta\left(1-\frac{\dot{p}}{\mu+j+\left(\mu+p_{2}\right) \theta}\right)+\left(\frac{\dot{i}}{\dot{\mu}+1 i+(\mu+12) \theta}\right)^{\prime}
\end{aligned}
$$

For

$$
\begin{aligned}
\mu>k \quad(\dot{\mu}+\dot{k}) & =\theta[1-(\mu+h)] \\
\therefore(\mu+k) & \rightarrow 1
\end{aligned}
$$

Thus, small perturbations of density die away. Moreover equation (18) still holds, and therefore rotational perturbations also die away. Equation (19) now becomes

$$
\begin{aligned}
& \dot{\theta}=-\frac{1}{3} \theta^{2}-\frac{1}{2}(\mu+3 \mu)+1 \\
\therefore \quad \theta & \rightarrow \sqrt{3\left(\frac{1}{2}-12\right)}
\end{aligned}
$$

These results confirm those obtained by Hoyle and Narlikar ${ }^{(14)}$. We see therefore that galaxies cannot be formed in the steady-state universe by the growth of small perturbations. However this does not exclude the possibility that there might by a self-perpetuating system of Iinite perturbations which could produce galaxies. (Sciama ${ }^{(15)}$, Roxburgh and Saffman ${ }^{(16)}$ ).

## 8. Gravitational Vaves

We now consider perturbations of the Weyl tensor that do not arise from rotational or density perturbations, that is,

$$
E_{a b^{; b}}=H_{a b^{j b}}=0
$$

Multiplying (15) by $u^{c} \nabla_{c}$, and (16) by $h^{a}\left(\cdot \rho_{q}\right)^{r b s} u_{r} \nabla_{s}$ :
we obtain, after a lot of reduction,
$E_{a b}-\left(E_{c d ; e} h_{f}^{c} h_{g}^{d} h_{k}^{e}\right) ; i h^{k i} h_{a}^{t} h_{b}^{g}+\frac{7}{3} E_{a b} \theta$
$+E_{a b}\left(\dot{\theta}+\frac{4}{3} \theta^{2}+\frac{1}{3}(\mu-3 p)\right)+\sigma_{a b}\left[\frac{1}{3} \theta(\mu+12)+\frac{1}{2}(\dot{\mu}+\dot{p})\right]=0$

In empty space with a non-expanding congruence $U^{a}$ this reduces to the usual form of the linearised theory,

$$
\square^{2} E_{a b}=0
$$

The second term in (24) is the Laplacian in the hypersurface $\tau=$ constant, acting on E E . We will write Ebb as a sum of eigensfunctions of this operator.

$$
E_{a b}=\sum A^{(n)} V_{a b}^{(n)}
$$

where

$$
\text { Then } \quad \dot{E} a b=\sum \frac{A^{\prime(n)}}{\Omega} V_{a b}^{(n)}
$$

$$
\begin{aligned}
& \dot{V}_{a b}{ }^{(n)}=0 \text {, } \\
& \left(V_{c d} ; \ln _{f}^{c} h_{g}^{d} h_{k}^{e}\right) ; i h^{k i} h_{a}^{f} h_{b}^{g}=\frac{-n^{2}}{S^{2}} V_{a b}{ }^{(n)} \text {, } \\
& V_{a b^{; b}}=0, \quad V_{a}^{a}=0 \\
& E_{a b}=\sum\left[\frac{A^{\prime \prime}(n)}{S L^{2}}-\frac{A^{\prime(n)} Z^{\prime}}{S 2^{2}}\right] V_{a}^{\left(n^{\prime}\right.}
\end{aligned}
$$

Similarly,

$$
\sigma_{a b}=\sum D^{(n)} V_{a b}^{(n)}
$$

Then by (19)

$$
D^{\prime(n)}=\Omega A^{(n)}-2 D^{(n)} \frac{\Omega^{\prime}}{\Omega}
$$

Substituting in (24)

$$
\begin{aligned}
A^{\prime \prime}(n) & +\frac{6 \Omega \Omega^{\prime}}{\Omega} A^{\prime(n)}+A^{(n)}\left[n^{2}+3 \frac{\Omega^{\prime \prime}}{\Omega}+6 \frac{\Omega^{\prime 2}}{\Omega^{2}}+\frac{1}{3}(\mu+3 h) \Omega^{2}\right] \\
& +D^{(n)}\left[\Omega^{\prime}(\mu+/ 2)+\frac{1}{2} \Omega^{2}(\mu+\dot{i})\right]=0
\end{aligned}
$$

We may differentiate again and substitute for $D^{\prime}$,

$$
\begin{aligned}
\text { For } & \begin{array}{l}
n \gg 1 \\
\text { and } \\
\\
\\
A^{(n)}
\end{array} \quad=\frac{1}{\Omega^{3}} e^{i n t}
\end{aligned}
$$

so the gravitational field $E_{a b}$ decreases as $\Omega^{-1}$ and the "energy" $\frac{1}{2}\left(\mathrm{E}_{a b} \mathrm{E}^{\mathrm{ab}}+\mathrm{H}_{a b} H^{a b}\right)$ as $\Omega^{-6}$. We might expect this as the Bianchi identities may be written, to the linear approximation,

$$
\Omega g^{e d} \frac{\partial}{\partial x^{e}}\left(\Omega^{-1} C_{a b c d}\right)=J a b c
$$

Therefore if the interaction with the matter could be neglected $C_{\text {abed }}$ would be proportional to $\Omega$ and $E_{a b}, H_{a b}$ to $\Omega^{-1}$.

In the steady-state universe when $\mu$ and $\theta$ have reached their equilibrium values, $\quad R_{a b}=\left(\frac{1}{2}+12 / g_{a b}\right.$

$$
\therefore J_{a b c}=R_{c}[a ; b]-\frac{1}{6} g c\left[a R_{;} b\right]
$$

$=0$

Thus the interaction of the "C" field with gravitational radiation is equal and opposite to that of the matter. There is then no net interaction, and $E_{a b}$ and $H_{a b}$ decrease as $\Omega^{-1}$.

The "energy" $\frac{1}{2}\left(\mathrm{E}_{a b^{5}} \mathrm{ab}+H_{a b} H^{a b}\right)$ depends on second derivatives of the metric. It is therefore proportional to the frequen squared times the energy as measured by the energy momentum pseudo-tensor, in a local co-moving Cartesian coordinate system which depends only on first derivatives. Since the frequency will be inversely proportional to $\Omega$, the energy measured by the pseudo-tensor will be proportional to $\Omega^{-4}$ as for other rest mass zero fields.
9. Absorption of Gravitational Waves

As we have seen, gravitational waves are not absorbed by a perfect fluid. Suppose however there is a small amount of viscosity. We may represent this by the addition of a term $\lambda \sigma_{a b}$ to the energy-momentum tensor, where $\lambda$ is the coefficient of viscosity (inlers, (17)).

$$
\text { Since } \quad T_{a b} ; b=0
$$

we have

$$
\begin{align*}
& \dot{\mu}+(\mu+h) \theta-2 \lambda \sigma^{2}=0  \tag{25}\\
& (\mu+h) \dot{u}_{a}+h_{b} h_{a}^{b}+\lambda \sigma_{c b} ; b h_{a}^{c}=0 \tag{26}
\end{align*}
$$

Fquations (15) (16) become

$$
\begin{align*}
\dot{E}_{a b}+E_{a b} \theta+h^{f}(a \eta b) c d e u^{c} H_{f}^{d j e} & =-\frac{1}{2}(\mu+h) \sigma_{a b} \\
& -\frac{1}{2} \lambda\left(E_{a b}-\frac{1}{3} \sigma_{a b} \theta\right) . \tag{27}
\end{align*}
$$

$$
\begin{equation*}
\dot{H}{ }_{a b}+H_{a b} \theta-h^{f}(a \eta b) c d e u^{c} E_{f}^{\alpha ; e}=-\frac{1}{2} \lambda H_{a b} \tag{28}
\end{equation*}
$$

The extra terms on the right of equations (27), (28) are similar to conduction terms in Maxwell's equations and will cause the wave to decrease by a factor $e^{-\frac{\lambda}{2} t}$. Neglecting expansion for the moment, suppose we have a wave of the form,

$$
E_{a b}=E_{a b} e^{i \nu \tau} .
$$

This will be absorbed in a characteristic time $2 / \lambda$ independent of frequency. By (25) the rate of gain of rest mass energy of the matter will be $2 \lambda \sigma^{2}$ which by (19) will be $2 \lambda E_{0}^{2} \nu^{-2}$. Thus the available energy in the wave is $40 E^{2} \nu^{-2}$. This confirms that the density of available energy of gravitational radiation will decrease as $\Omega^{-4}$ in an expanding universe. From this we see that gravitational radiation behaves in much the same way as other radiation fields. In the early stages of an evolutionary universe when the temperature was very high we might expect an equilibrium to be set up between black-body electromagnetic; diation and black-body gravitational radition. Since they both have two polarisations their
energy densities should be equal. As the universe expanded they woul. both cool adiabatically at the same rate. As we know the temperaturo of black-body extragalactic electromagnetic radiation is less than $5^{O_{K}}$, the temperature of the black-body gravitational radiation musú be also less than this which would be absolutely undetectable. Now the energy (f gravitational radistion does not contribute to the ordinary energy momentum tensor $T_{a b}$. Nevertheless it will have an active gravitational effect. By the expansion equation,

$$
\dot{\theta}=-\frac{1}{3} \theta^{2}-2 \sigma^{2}-\frac{1}{2}(\mu+3 \mu)
$$

For incoherent gravitational radiation at frequency $v$,

$$
\sigma^{2}={ }_{0} E^{2} V^{-2}
$$

But the energy density of the radiation is

$$
\therefore \quad \dot{\theta}=-\frac{1}{3} \theta^{2}-\frac{1}{2} \mu_{G}-\frac{1}{2}\left(\mu+3 \gamma_{2}\right)
$$

whers $\mu_{G}$ is the gravitational "energy" density. Thus gravitational radiation has an active attractive gravitational effect. It is interesting that this seems to be just half that of electromagnetic radiation.

It has been suggested by Hogarth ${ }^{(18)}$ and Hoyle and Narlikar (10), that there may be a connection between the absorption of radiation and the Arrow of Time. Thus in universes like the steady-state, in which all electromagnetic radiation emitted is ventually absorbed by other matter, the Absorber theory would predic retarded solutions of
the Maxwell equations while in evolutionary universes in which electromagnetic radiation is not completely absorbed it would predict advanced solutions. Similarly, if one accepted this theory, one would expect retarded solutions of the Binstein equations if and only if all gravitational radiation emitted is eventually absorbed by other matter. Clearly this is so for the steady-state universe since $\lambda$ will be constant. In evolutionary universes $\lambda$ will be a function of time. We will obtain complete absorption if $\int \lambda$ di $\tau$ diverges. Now fr ? a gas, $\lambda \propto T^{\frac{1}{2}}$ where $T$ is the temperature. For a monatomic gas, $T \propto \Omega^{-2}$, therefore the integral will diverge (just). However the expression used for viscosity assumed that the mean free path of the atoms was small compared to the scale of the disturbance. Since the mean free path $\propto \mu^{-1} \propto \Omega^{-3}$ and the wavelength $\propto \Omega^{-1}$, the mean free path will eventually be greater than the wavelength and so the effective viscosity will decrease more rapidly than $\Omega^{-1}$. Thus there will not be complete absorption and the theory would not predict retarded solutions.

However this is slightly academic since gravitational radiation has not yet been detected, let alone investigated to see whether it corresponds to a retarded or advanced solution.

## Gravitational Radiation In An

Expanding Universe

Gravitational radiation in empty asymptotically flat space has been examined by means of asymptotic expansions by a number of authors. (1-4) They find that the different components of the outsoing radiation ficld "peel off", that is, they go as different powers of the affine radial distance. If one wishes to investigate how this behaviour is modified by the presence of matter, one is faced with a difficulty that does not arise in the case or, say, electromagnetic radiation in matter. For this one can consider the radiation travelling through an infinite uniform medium that is static apart from the disturbance created by the radiation. In the case of gravitational radiation this is not possible. For, if the medium were initially static, its own self gravitation would cause it to contract in on itself and it would cease to be static. Hence one is forced to investigate gravitational radiation in matter that is either contracting or expanding. AS in Chapter 2, we identify the Weyl or conformal tensor whul with the free gravitational field and the Ricci-tensor $R_{a b}$ with the contribution of the matter to the curvature. Instead of considerins gravitational radiation in
asymptotically flat space, that is, space that approaches flat space at large radial distances, we consider it in asymptotically conformally flat space. As it is only conformally flat, the Ricci-tensor and the density of matter need not be zero.

To avoid essentially non-gravitational phenomena such as sound waves, we will consider gravitationalradiation travelling through dust. It was shown in Chapter 2 that a conformally flat universe filled with dust must have one of the metrics:
(a) $\quad d s^{2}=\Omega^{2}\left(d t^{2}-d p^{2}-\sin ^{2} p\left(d \theta^{2}+\sin ^{2} \theta d \phi^{2}\right)\right)$

$$
\Omega=A(1-\cos t)
$$

(b) $d s^{2}=\Omega^{2}\left(d t^{2}-d p^{2}-\rho^{2}\left(d \theta^{2}+\sin ^{2} \theta d \phi^{2}\right)\right)$

$$
\begin{equation*}
\Omega=\frac{1}{2} A t^{2} \tag{1,2}
\end{equation*}
$$

(c) $d s^{2}=\Omega^{2}\left(d t^{2}-d \rho^{2}-\sinh { }^{2} p\left(d \theta^{2}+\sin ^{2} \theta d \phi^{2}\right)\right)$

$$
\Omega=A(\cosh t-1) \quad(1.3)
$$

Type (a) represents a universe in which the matter expands from the initial singularity with insufficient energy to reach infinity and so falls back again to another singularity. It is therefore unsuitable for a discussion of
gravitational radiation by a method of asymptotic expansions since one cannot jet an infinite distance from thie source.

Type (b) is the Einstein-De Sitter universe in which the matter has just sufficient energy to reach infinity. It is thus a special case. D. Norman (5) has investigated the "peeling off" behaviour in this case using Penrose's conformal technique (6). He was however forced to make certain assumptions about the movement of the matter which will be shown to be false. Moreover, he was misled by the special nature of the Einstein-De Sitter universe in which affine and luminosity distances differ. Another reason for not considering radiation in the Einstein-De Sitter universe is that it is unstable. The passage of a gravitational wave will cause it to contract again eventually and develop a singularity.
we will therefore consider radiation in a universe of type (c) which corresponds to the general case where the matter is expanding with more than enough energy to avoid contractin\% again.
2. The Newman-Penrose Formalism

We employ the notation of Newman and Penrose. (3) A tetrad of null vectors, $L^{\mu}, \Omega^{\mu}, M^{\mu}, \bar{m} \mu$ is introduced
where:

$$
\begin{aligned}
& l_{\mu} L^{\mu}=n_{\mu} n^{\mu}=m_{\mu} m^{\mu}=l_{\mu} m^{\mu}=n_{\mu} m^{\mu}=0 \\
& l_{\mu} n^{\mu}=1, \quad M_{\mu} \bar{m}^{\mu}=-1
\end{aligned}
$$

we label these vectors with a tetrad index

$$
z_{a}^{\mu}=\left(L, n^{\mu} M^{\mu}, \bar{M}^{\mu}\right)^{\text {m }} \quad a=1,2,3,4
$$

tetrad indices are raised and lowered with the metric

$$
\eta=\eta^{a b}=\left[\begin{array}{cccc}
0 & 1 & 0 & 0  \tag{2.1}\\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 \\
0 & 0 & -1 & 0
\end{array}\right]
$$

we have, $g^{\mu v}=\eta_{a}^{a b} z_{a}^{\mu} z_{b}^{v}$

$$
=L^{\mu} n^{v}+n^{\mu} L^{v}-m^{\mu} \bar{m}^{v}-\bar{m}^{\mu} m^{v} \text { (2.2) }
$$

Ricci rotation coefficients are defined by:

$$
\begin{equation*}
\gamma_{a}^{b}={\underset{a}{a} \mu i v}^{z^{b} \mu} z^{c} v \tag{2.3}
\end{equation*}
$$

In fact it is more convenient to work in terms of twelve complex combinations of rotation coefficients defined as

$$
\begin{aligned}
& \text { follows: } \\
& K=\underset{13 i}{\gamma}=L_{\mu, \nu} m^{\mu} L^{v} \\
& \pi=-\gamma_{241}=-n_{\mu i v} \bar{m}^{\mu} L^{v} \\
& \varepsilon=\frac{1}{2}\left(\begin{array}{c}
\gamma \\
L_{1}
\end{array}-\underset{341}{\gamma}\right)=\frac{1}{2}\left(L_{\mu ; \nu} n^{\mu} L^{\nu}-\eta_{\mu ; v} \bar{m}^{\mu} L^{\nu}\right) \\
& \rho=\gamma_{134}^{\gamma}=L_{\mu i v} m^{\mu} \bar{m}^{\nu} \\
& \lambda=-{ }_{244}^{\gamma}=n_{\mu ; \nu} \bar{m}^{\mu} \bar{m}^{v} \\
& \alpha=\frac{1}{2}\left(\begin{array}{c}
244 \\
\gamma
\end{array}-\gamma \quad \begin{array}{l}
344
\end{array}\right)=\frac{1}{2}\left(L_{\mu ; v} n^{\mu} \bar{m}^{v}-m_{\mu ; v} \bar{m}^{\mu} \bar{m}^{v}\right) \\
& \beta=\frac{1}{2}\left(\begin{array}{c}
\gamma \\
123
\end{array}-\begin{array}{r}
\gamma 43
\end{array}\right)=\frac{1}{2}\left(L_{\mu i v} n^{\mu} m^{\nu}-m_{\mu ; \nu} M^{\mu} m^{\nu}\right)
\end{aligned}
$$

$$
\begin{align*}
& \mu=-{ }_{243}=-n_{\mu i v} \bar{M}^{\mu} M^{\nu} \\
& v=-\frac{\gamma}{242}=-n_{\mu} ; v \bar{m}^{\mu} n^{v} \\
& \gamma=\frac{1}{2}\left(\begin{array}{c}
\gamma \\
122
\end{array}-\gamma \begin{array}{l}
34^{2}
\end{array}\right)=\frac{1}{2}\left(L_{\mu ; v} n^{\mu} n^{v}-M_{\mu_{i}, ~} \mu^{\mu} n^{\nu}\right) \\
& \tau=\gamma_{i 32}^{\gamma}=L_{\mu ; v} M^{\mu} n^{v} \tag{2.4}
\end{align*}
$$

3. Coordinates

Like Newman and Penrose, we introduce a null coordinate

$$
u\left(=x^{\prime}\right)
$$

$$
\begin{equation*}
g^{\mu v} u_{; \mu} u_{; v}=0 \tag{3.1}
\end{equation*}
$$

we take $L_{\mu}=U ; \mu$. Thus $L_{\mu}$ will be geodesic and irrotational. This implies

$$
\begin{align*}
& K=0 \\
& \rho=\bar{\rho}  \tag{3.2}\\
& \varepsilon=-\bar{\varepsilon}
\end{align*}
$$

we take $n^{\mu}, M^{\mu}, \bar{m}^{\mu}=\dot{\alpha}+\beta$ to be parallelly transported along $L^{\mu}$. This gives

$$
\begin{equation*}
\pi=\varepsilon=0 \tag{3.3}
\end{equation*}
$$

As a second coordinate we take an affine parameter or $\left(=x^{2}\right)$ long the geodesics $L \mu$
$X^{3}$ and $x^{4}$ are two coordinates that label the geodesic in the surface $U=$ const.
Thus $g^{\mu \nu} \quad X_{i j \mu}^{3} L^{\mu}=X_{i}^{4} ; L^{\mu}=0$

In these coordinates $\left[g^{26} g^{34} g^{44}\right.$

$$
\begin{aligned}
& {\left[O g^{24} g^{34} g^{i 4} L_{\mu}=\delta_{\mu}^{\prime} L^{\mu}=\delta_{2}^{\mu}\right.} \\
& \text { coordinates } \\
& \text { since } L_{\mu} n^{\mu}=1, L_{\mu}^{\mu} M^{\mu}=0 \\
& M^{\mu}=\omega \delta_{2}^{\mu}+\xi^{i} \delta_{i}^{\mu} \\
& n^{\mu}=\delta_{i}^{\mu}+U \delta_{2}^{\mu}+X^{i} \delta_{i}^{\mu} \quad i=3,4 \quad \text { (3.7) }
\end{aligned}
$$

We may calculate the Ricci and Weal tensor components from

Using the combinations of rotation coefficients already
defined and with $K=\Pi=\varepsilon=0$ we have

$$
\begin{align*}
& \text { 1) } p=\rho^{2}+\sigma \bar{\sigma}+\phi_{00}  \tag{3.10}\\
& D_{\sigma}=2 \rho \sigma+\psi_{0} \\
& D \tau=\tau \rho+\bar{\tau} \sigma^{2}+\psi_{1}+\phi_{01}  \tag{3.12}\\
& D \alpha=\alpha \rho+\beta \bar{\sigma}+\phi_{10} \\
& D \beta=\beta \rho+\alpha \sigma+\psi_{1} \\
& D \gamma=\tilde{\tau} \alpha+\bar{i} \beta+\psi_{2}-\Lambda+\phi_{11}  \tag{3.15}\\
& D \lambda=\lambda \rho+\mu \bar{\sigma}+\phi_{20} \\
& D \mu=\mu \rho+\lambda \sigma+\psi_{2}+2 \Lambda \\
& D v=\tau \lambda+\bar{\tau} \mu+\psi_{3}+\phi_{21} \\
& \text { (3.13) } \\
& (3,14) \\
& \text { (3.16) } \\
& \text { (3.17) } \\
& \text { (3.18) }
\end{align*}
$$

$$
\begin{align*}
& \Delta \lambda-\bar{\delta}_{v}=2 \alpha v+(\bar{\gamma}-3 \gamma-\mu-\bar{\mu}) \lambda-\psi_{4} \quad \text { (3 19) } \\
& \delta_{\rho}-\bar{\delta}_{\sigma}=(\beta+\bar{\alpha}) \rho+(\bar{\beta}-3 \alpha) \sigma-\psi_{1}+\phi_{01} \quad \text { (3.20) } \\
& \delta_{\alpha}-\bar{\delta}_{\beta}=\mu \rho-\lambda \sigma-2 \alpha \beta+\alpha \bar{\alpha}+\beta \bar{\beta}-\psi_{2}+\Lambda+\phi_{11} \text { (3.21) }  \tag{3.20}\\
& \delta_{\lambda}-\bar{\delta}_{\mu}=(\alpha+\bar{\beta}) \mu+(\bar{\alpha}-3 \beta) \lambda-\psi_{3}+\phi_{21} \quad \text { (322) 22) } \\
& \delta_{v}-\Delta \mu=\gamma \mu-2 \nu \beta+\overline{\gamma \mu}+\mu^{2}+\lambda \bar{\lambda}+\phi_{22} \quad \text { (3.23) } \\
& \delta_{\gamma}-\Delta \beta=\tau \mu-\sigma v+(\mu-\gamma+\bar{\gamma}) \beta+\bar{\lambda} \alpha+\phi_{12}(324)  \tag{3.23}\\
& \delta_{\tau}-\Delta \sigma=2 \tau \beta+(\bar{\gamma}+\mu-3 \gamma) \sigma \tau \bar{\lambda} \rho+\phi_{02} \quad \text { (3.25) } \\
& \Delta \rho-\bar{\delta}_{\tau}=(\gamma+\bar{\gamma}-\bar{\mu}) \rho-2 \alpha \tau-\lambda_{\sigma}-\psi_{2}-2 \Lambda \text { (3.26) } \\
& \Delta \alpha-\delta_{\gamma}=\rho v-\tau \lambda-\lambda \beta \\
& \quad+(\bar{\gamma}-\gamma-\bar{\mu}) \alpha-\psi_{3} \tag{3.27}
\end{align*}
$$

where

$$
\begin{align*}
& D=L^{\mu} \nabla_{\mu}=\frac{\partial}{\partial r}  \tag{3.28}\\
& \Delta=n^{\mu} \nabla_{\mu}=V \frac{\partial}{\partial \mu}+\frac{\partial}{\partial u}+X^{i} \frac{\partial}{\partial x^{i}}(\underline{(329)} \\
& \delta=m^{\mu} \nabla_{\mu}=\omega \frac{\partial}{\partial r}+\xi^{i} \frac{\partial}{\partial x^{i}} \\
& \phi_{00}=-\frac{1}{2} R=\bar{\phi}_{00}  \tag{3.3i}\\
& \phi_{11}=-\frac{1}{4}\left(R+\frac{R}{12}\right)  \tag{3.32}\\
& \phi_{01}=-\frac{1}{2} R=\bar{\phi}_{13}^{R}=\bar{\phi}_{10}  \tag{3.33}\\
& \phi_{12}=-\frac{1}{2} R=\bar{\phi}_{21}  \tag{3.34}\\
& \phi_{02}=-\frac{1}{2} R=\bar{\phi}_{20}  \tag{3.35}\\
& \phi_{22}=-\frac{1}{2} R=\bar{\phi}_{22}  \tag{3.36}\\
& \Lambda=\frac{(3.32)}{24} \tag{3.37}
\end{align*}
$$

$$
\begin{align*}
& \psi_{0}=-{ }_{13,3}^{-C}=-C_{\alpha \beta \gamma \delta} L^{\alpha} m^{\beta} L^{\gamma} m^{\delta}  \tag{3.38}\\
& \Psi_{1}=-\underset{12,3}{C}=-C_{\alpha \beta \gamma \delta} L^{\alpha} n^{\beta} L^{\gamma} m^{\delta}  \tag{3.39}\\
& \psi_{2}=-\frac{1}{2}\left(c_{1212}+{ }_{1234}^{c}\right)=-\frac{1}{2} c_{\alpha \beta \gamma \delta} \\
& x\left(L^{\alpha} n^{\beta} L^{\gamma} n^{\delta}+L^{\alpha} n^{\beta} n^{\gamma} \bar{m}^{\delta}\right)  \tag{3.40}\\
& \psi_{3}=C_{1224}=C_{\alpha \beta \gamma^{\delta}} L^{\alpha} n^{\beta} n^{\gamma} m^{\delta}  \tag{3.41}\\
& \psi_{4}=\frac{-C}{2424}=-C_{\alpha \beta \gamma} \delta n^{\alpha} \bar{m}^{\beta} n^{\gamma} \bar{m}^{\delta} \tag{3.42}
\end{align*}
$$

Expressing $\overline{5}$ the rotation coefficients in terms of the metric, we have:

$$
\begin{align*}
& D \bar{\xi}^{i}=\rho \xi^{i}+\sigma \bar{\xi}^{i}  \tag{3.13}\\
& D \omega=\rho \omega+\sigma \bar{\omega}-(\bar{\alpha}+\beta) \quad \underline{(3.44)} \\
& D X^{i}=\tau \bar{\xi}^{i}+\bar{i} \xi^{i} \quad \underline{(3.65)} \\
& D U=\tau \bar{\omega}+\bar{\omega} \omega-(\gamma+\bar{\gamma}) \quad(\underline{(3.46)} \\
& \delta X^{i}-\Delta \xi^{i}=(\mu+\bar{\gamma}-\gamma) \xi^{i}+\bar{\lambda} \bar{\xi}(3.47) \\
& \bar{\delta} \xi^{i}-\bar{\delta} \xi^{i}=(\bar{\beta}-\alpha) \xi^{i}+(\bar{\alpha}-\beta) \bar{\xi}^{i}(3.48) \\
& \delta \bar{\omega}-\bar{\delta} \omega=(\bar{\beta}-\alpha) \omega+(\bar{\alpha}-\beta) \bar{\omega}+(\mu-\bar{\mu})(3.49) \\
& \delta U-\Delta \omega=(\mu+\bar{\gamma}-\gamma) \omega+\bar{\lambda} \bar{\omega}-\bar{\gamma} \quad \text { (3.50) }
\end{align*}
$$

As in Chapter 2 we use the Bianchi identities as field equations for the weyl tensor. In the Newman-Penrose formalism they may be written:
(I am indebted to R. G. Mcienashan for these)

$$
\begin{align*}
& \bar{\delta} \psi_{0}-D \psi_{1}+D \phi_{\text {or }}-\delta \phi_{00}=4 \alpha \psi_{0}-4 \rho \psi_{1}-(2 \bar{\alpha}+\beta) \phi_{00} \\
& +2 \rho \phi_{01}-26 \phi_{10}  \tag{3.51}\\
& \Delta \psi_{0}-\delta \psi_{i}{ }^{+} D \phi_{02}-\delta \phi_{01}=(4 \gamma-\mu) \psi_{0}-2(2 \tau+\beta) \psi_{i} \\
& +36 \psi_{2}-\bar{\lambda} \phi_{00}-2 \beta \phi_{01}+26 \phi_{11}+\rho \phi_{02} \text { (3.52) } \\
& 3\left(\bar{\delta} \psi_{1}-D \psi_{2}\right)+2\left(D \phi_{1}-\delta \phi_{10}\right)+\bar{\delta} \phi_{0,}-\Delta \phi_{00}=3 \lambda \psi_{0}-9 p \psi_{2} \\
& +6 \alpha \psi_{1}+(\bar{\mu}-2 \mu-2 \gamma-2 \bar{\gamma}) \phi_{00}+(2 \alpha+2 \bar{\varepsilon}) \phi_{01} \\
& { }^{2} 2(\tau-2 \bar{\alpha}) \phi_{10}+2 \rho \phi_{11}+2 \sigma \phi_{20}-\bar{\sigma} \phi_{02}  \tag{3.53}\\
& 3\left(\Delta \psi_{1}-\delta \psi_{2}\right)+2\left(D \phi_{12}-\delta \phi_{11}\right)+\left(\bar{\delta} \phi_{02}-\Delta \phi_{01}\right)=3 r \psi_{0}+ \\
& +6(\gamma-\mu) \psi_{1}-9 \tau \psi_{2}+6 \sigma \psi_{3}-\nabla \phi_{00} \\
& +2(\bar{\mu}-\mu-\gamma) \phi_{01}-2 \lambda \phi_{10}+2 \dot{\psi} \phi_{11} \\
& +(2 \alpha+\bar{c}-2 \bar{\beta}) \phi_{02}+2 \sigma \phi_{\alpha 1}  \tag{3.54}\\
& 3\left(\bar{\delta} \psi_{2}-D \psi_{3}\right)+\left(D \phi_{21}-\delta \phi_{20}\right)+2\left(\delta \phi_{11}-\Delta \phi_{10}\right)=6 \lambda \psi_{.} \\
& -6 p \psi_{3}-2 r \phi_{00}+2 \lambda \phi_{01}+2(\bar{\mu}-\mu-2 \bar{\gamma}) \phi_{10} \\
& +4 \bar{\varepsilon} \phi_{11}+(2 \beta+2 \dot{c}-2 \bar{\alpha}) \phi_{20}-2 \bar{\sigma} \phi_{12} \tag{3.55}
\end{align*}
$$

$$
\begin{align*}
& 3\left(\Delta \psi_{2}\right.\left.-\delta \psi_{3}\right)+\left(D \phi_{22}-\delta \phi_{21}\right)+2\left(\bar{\delta} \phi_{12}-\Delta \phi_{11}\right) \\
&=6 v \psi_{1}-9 \mu \psi_{2}+6(\beta-\tau) \psi_{3}-3 \sigma \psi_{4} \\
&-2 v \phi_{01}-2 \bar{r} \phi_{10}+2(2 \bar{\mu}-\mu) \phi_{11}+2 \lambda \phi_{02} \\
&-\lambda \phi_{20}+2(\bar{c}-2 \bar{\beta}) \phi_{12}+2\left(\beta_{r} \tau\right) \phi_{21}-\rho \phi_{22}  \tag{3.56}\\
& \bar{\delta} \psi_{3}- D \psi_{4}+\bar{\delta} \phi_{21}-\Delta \phi_{20}=3 \lambda \psi_{2}-22 \psi_{3}-\rho \psi_{4} \\
&-2 v \phi_{01}+2 \lambda \phi_{11}+(2 \gamma-2 \bar{\gamma} \tau \bar{\mu}) \phi_{20} \\
&+2(\bar{\tau}-\alpha) \phi_{21}-\bar{\sigma} \phi_{22}(3.57) \\
& \Delta \psi_{3}-\delta \psi_{4}+\bar{\delta} \phi_{22}-\Delta \phi_{21}=3 v \psi_{2}-2(\gamma+2 \mu) \psi_{3} \\
&+(4 \beta-\tau) \psi_{4}-2 v \phi_{11}-\bar{v} \phi_{20}+2 \lambda \phi_{12} \\
&+2(\gamma+\mu) \phi_{21}+(\bar{\tau}-2 \bar{\beta}-2 \alpha) \phi_{22}
\end{align*}
$$

$$
\begin{align*}
& D \phi_{12}-\delta \phi_{11}-\bar{\delta} \phi_{02}+\Delta \phi_{01}+3 \delta \Lambda=(2 \gamma-\mu-2 \bar{\mu}) \phi_{01}+\bar{r} \phi_{00} \\
&-\bar{\lambda} \phi_{10}-2 \tau \phi_{11}+(2 \bar{\beta}-2 \alpha-\bar{\tau}) \phi_{02}+3 \rho \phi_{12}+\sigma \phi_{21}(\underline{3.5 q)} \\
& D \phi_{11}-\delta \phi_{10}-\bar{\delta} \phi_{01}+\Delta \phi_{00}+3 D \Lambda=(2 \gamma-\mu+2 \bar{\gamma}-\bar{\mu}) \phi_{00}-2(\alpha+\bar{\tau}) \phi_{01} \\
&-2(\overline{\alpha r} \tau) \phi_{10}+4 \rho \phi_{11}+\bar{\sigma} \phi_{02}+\sigma \phi_{20} \quad(3.60) \\
& D \phi_{22}-\delta \phi_{21}-\bar{\delta} \phi_{12}+\Delta \phi_{11}+3 \Delta \Lambda=v \phi_{01}+\bar{v} \phi_{10}-2(\mu+\bar{\mu}) \phi_{11}  \tag{3.60}\\
&-\lambda \phi_{02}-\bar{\lambda} \phi_{20}+(2 \bar{\beta}-\bar{\tau}) \phi_{12}+(2 \beta-\tau) \phi_{21} \\
&+2 \rho \phi_{22}
\end{align*}
$$

## 4. The Undisturbed Metric

The undisturbed metric may be written
$d s^{2}=\Omega^{2}\left(d t^{2}-d \rho^{2}-\sinh ^{2} p\left(d \theta^{2}+\sin ^{2} d \phi^{2}\right)\right)$ $\Omega=A(\cos h t-1)$
put $u=t-p$
then $d s^{2}=\Omega^{2}\left[-d u^{2}+2 d u d t-\sinh 2(t-u)\left(d \theta_{+}^{2} \sin ^{2} \theta_{d} d \phi^{2}\right)\right]$
$u$ is a null coordinate
To calculate $\mu$, the affine parameter, we note that $\mathcal{E}$ is an affine parameter for the metric within the square brackets. Therefore $q=\int \Omega^{2} d t+\bar{B}(u, \theta, \phi) \quad$ (4.2) will be an affine parameter for $(4 \cdot 1)$
$B$ is constant along the null geodesic. Normally it would be taken so that $r=0$ when $t=u$. However, in our case it will be more convenient to make it zero and define $V$ as

$$
t=\int_{0}^{E} \Omega^{2} d t^{\prime}
$$

This means that surfaces of constant $r$ are surfaces of constant $t$. This may seem rather odd, but it should be pointed out that the choice of $Z$ will not affect the asymptotic dependence of quantities. That is, if

$$
f=O\left(r^{-n}\right)
$$

Then

$$
f=O\left(r^{\prime-n}\right), \quad r^{\prime}=r+B
$$

It proves easier to perform the calculations with this choice of $r$ but all results could be transformed back to a more normal coordinate system.
$\operatorname{From}(4.3) \quad q=A^{2}\left[\frac{1}{4} \sinh 2 t-2 \sinh t \times \frac{3}{2} t\right]$

The matter in the universe is assumed to be dust so its energy tensor may be written

$$
\begin{equation*}
T_{a b}=\mu \dot{V}_{c} V_{b} \tag{4.5}
\end{equation*}
$$

For the undisturbed case, from Chapter 2

$$
\begin{aligned}
\mu & =\frac{6 A}{\Omega^{3}} \\
V_{a} & =\Omega t_{j a} \quad V_{a} V^{a}=1
\end{aligned}
$$

Now $\Omega=\sqrt{2} 5+A-\frac{3 A^{2}}{\sqrt[2]{2}} \frac{\log 5}{5}+O\left(5^{-1}\right) \quad(4.7)$ where $\quad S^{2}=4$
Therefore if we try to expand $\mu$ as a series in powar of $s$ the result will be very messy and will involve terms of the form

$$
\frac{\log ^{n} s}{s^{n}}
$$

* It should be pointed out that the expansions used will only be assumed to be valid asymptotically. They will not be assumed to converge at finite distances nor will the quantities concerned be assumed analytic. (see A. Erdelyi: Asymptotic Expansions - Dover

This does not invalidate it as an asymptotic expansion but it makes it tedious to handle. For convenience therefore, we will perform the expansions in terms of $\Omega(r)$ which will be defined in general as the same function of $\mu$ as it is in the undisturbed case. That is
where $T=A^{2}\left[\frac{1}{4} \sinh 2 t-2 \sinh t+\frac{3}{2} t\right] \quad$ (4.8)
then

$$
\begin{aligned}
\frac{d \Omega}{d r} & =\frac{\sqrt{1+\frac{2 A}{\Omega}}}{\Omega} \\
& \left.=\frac{1}{\Omega}\left[1+\frac{A}{\Omega}-\frac{A^{2}}{2 \Omega^{2}}+\frac{A^{3}}{2 \Omega^{3}}-\frac{5 A^{4}}{8 \Omega^{4}}+\frac{7 A^{5}}{8 \Omega^{5}}\right]\right](4.9)
\end{aligned}
$$

For the third and fourth coordinates it is more convenient to use stereographic coordinates than spherical polers.

Since the matter is dust its energy-momentum tensor and hence the Ricci-tensor have only four independent components. We will take these as $\Lambda, \phi_{00}, \phi_{01}$ (since $\phi_{01}$ is complex it represents two components) In terms of these the other components of the Ricci-tensor may be expressed as:

$$
\begin{aligned}
& \text { expressed as: } \\
& \phi_{11}=3 \Lambda+\frac{\phi_{01} \bar{\phi}_{01}}{\phi_{00}} \\
& \phi_{22}=\frac{36 \Lambda^{2}}{\phi_{00}}\left(1+\frac{\phi_{01} \bar{\phi}_{01}}{6 \Lambda \phi_{00}}\right)^{2}
\end{aligned}
$$

$$
\begin{aligned}
& \phi_{12}=\bar{\phi}_{21}=\frac{6 \wedge \phi_{01}}{\phi_{00}}\left(1+\frac{\phi_{0,} \bar{\phi}_{01}}{6 \wedge \cdot \phi_{00}}\right)^{2} \\
& \phi_{02}=\bar{\phi}_{20}=\frac{\phi_{01}{ }^{2}}{\phi_{00}}
\end{aligned}
$$

For the undisturbed universe with the coordinate system given:

$$
\begin{align*}
& \Lambda=\frac{\mu}{24}=\frac{A}{4 \Omega^{3}} \\
& \phi_{00}=\frac{3 A}{\Omega^{5}} \\
& \phi_{11}=\frac{3 A}{4 \Omega^{3}} \\
& \phi_{22}=\frac{3 A}{4 \Omega} \\
& \phi_{01}=\phi_{02}=0 \tag{4.11}
\end{align*}
$$

Using these values and the fact that in the undisturbed universe all the $\psi \stackrel{\omega}{ }$ are zero, we may integrate equations. (3. 10-50) to find the values of the spin coefficients for the unperturbed universe:

$$
\begin{aligned}
\rho= & -\frac{2}{\Omega^{2}}-\frac{A}{\Omega^{3}}+\left(\frac{A^{2}}{2}-\frac{A^{2}}{2} e^{2 u}\right) \Omega^{-4}- \\
& \left.A^{( } \frac{1}{2}-e^{2 u}\right) \Omega^{-5}+A^{4}\left(\frac{5}{8}-\frac{7}{4} e^{2 u}-\frac{1}{8} e^{4 u}\right) \Omega^{-6} \ldots . \\
\sigma= & \tau=\omega=v=\lambda=X^{4}=0 \\
\xi^{3}= & \frac{S e^{u}}{\Omega^{2}}-\frac{A S^{3 u}}{\Omega^{3}}+A^{4}\left(5 S A^{u}+S e^{3 u}\right) \Omega^{-4}+\ldots \ldots
\end{aligned}
$$

$\alpha=-\bar{B}=\frac{\frac{1}{2} \bar{\nabla} S_{e}{ }^{u}}{\Omega^{2}}-\frac{1}{2} \frac{A \bar{\nabla} S_{e}{ }^{u}}{\Omega^{3}}+$
$\mu=\frac{A}{2 \Omega}-\frac{\Omega^{2}}{4}\left(i+e^{2 u}\right) \Omega^{-2}+\frac{A^{3}}{4}\left(1+2 e^{2 u}\right) \Omega^{-3}+$
$\gamma=-\frac{1}{2}-\frac{A}{2 \Omega}+\frac{A^{2}}{4 \Omega^{2}}-\frac{A^{3}}{4 \Omega^{3}}+$
$U=\frac{1}{2} \Omega^{2}$
5. Boundary Conditions

We wish to consider radiation in a universe that asymptotically approaches the undisturbed universe given above.
 and will then have the values given above plus terms of smaller order. To determine this order and the order of $\phi_{01}$ and $\psi_{0}$, there are two ways in which we may proceed. We may take the smallest orders that will permit radiation, that is $\psi_{A}=O\left(r^{-1}\right)$. Larger order terms than these in
$\phi_{0}$ turn out to have their $u$ derivatives dependent only on themselves and not on the $r^{-1}$ coefficient of $\psi_{4}$, the radiation field. They are thus disturbances not produced by the radiation field and will not be considered. Alternatively we may proceed by a method of successive
approximations. We take the undisturbed values of the spin coefficients and use them to solve the Bianchi Identities as field equations for the conformal tensor using the flat space boundary condition that $\mathcal{Y}_{0}=O\left(r^{-5}\right)$. Then substituting these $\psi^{i s}$ in equations (3.i0-27) calculate the disturbandes induced in the spin coefficients and substituting these back in the Bianchi Identities, calculate the disturbances in the $\psi^{\prime s}$ - Further iteration does not affect the orders of the disturbances.

Both these methods indicate that the boundary conditions should be:

$$
\begin{align*}
& 1=\frac{A}{4 \sqrt{\Omega^{3}}}+o\left(\Omega^{-7}\right)  \tag{si}\\
& \phi_{00}=\frac{3 A}{\Omega^{5}}+O\left(\Omega^{-9}\right) \\
& \phi_{01}=O\left(\Omega^{-7}\right) \text { (see next section) } \\
& \psi_{0}=O\left(\Omega^{-7}\right)
\end{align*}
$$

We also assume"uniform smoothness", that is:

$$
\begin{aligned}
& \frac{\partial}{\partial x^{2}} \frac{\partial}{\partial x^{+}} \cdots \frac{\partial}{\partial x^{2}} \Lambda=O\left(\Omega^{-7}\right) \\
& \frac{\partial}{\partial \Omega} \Lambda=-\frac{3 A}{4 \Omega^{4}}+O\left(\Omega^{-8}\right)
\end{aligned}
$$

10 will be shown that if these boundary conditions hold on one hypersurface ( $u=$ const.) they will hold on succeeding hypersurfaces and that these conditions are the most severe to permit radiation.

## Integration

As Newman and Penrose, we begin by integrating the equations (3. 10 \& 11)

$$
\begin{aligned}
& D_{\rho}=\rho^{2}+\sigma \sigma^{2}+\phi_{00} \\
& D \sigma=2 \rho \sigma+\psi_{0}
\end{aligned}
$$

where

$$
\begin{aligned}
\phi_{00} & =\frac{3 A}{\sqrt{2} r \frac{5}{2}}+O\left(r^{-3}\right) \\
\psi_{0} & =\frac{\psi_{0}^{0}}{8 \sqrt{2}+\frac{7}{2}}+O\left(r^{-4}\right)
\end{aligned}
$$

Let

$$
P=\left[\begin{array}{ll}
\rho & \sigma \\
\bar{\sigma} & \rho
\end{array}\right] \quad \varphi=\left[\begin{array}{ll}
\phi_{00} & \psi_{0} \\
\psi_{0} & \phi_{00}
\end{array}\right]
$$

$$
\begin{aligned}
& \text { then } D P=P^{2} r \varphi \\
& \text { let } P=-(D y)^{-1} \\
& \text { then } D^{2} y=-\varphi y \\
& \text { since } \int r \varphi d r<\infty
\end{aligned}
$$

$$
D Y=F_{T} O(1)
$$

where $F$ is constant ( 6.4 )
However $\begin{aligned} \quad & =r F+O \\ Q & =O\left(r-\frac{5}{2}\right)\end{aligned}$
therefore $D^{2} y=-r \varphi F+O\left(r^{-\frac{3}{2}}\right)=O\left(r^{-\frac{3}{2}}\right)$
therefore $D Y=F+O\left(T^{-\frac{1}{2}}\right)$

$$
\begin{align*}
& y=r F+O\left(r^{\frac{1}{2}}\right)_{T} E \text { Ens constant } \\
& P=-T^{-1} I+O\left(r^{-\frac{s}{2}}\right) \tag{6.6}
\end{align*}
$$

if $\mathcal{F}$ is non-singular (The case $F$ singular corresponds to asymptotically plane or cylindrical surfaces and will not be considered here).
Thus $\rho=-\gamma^{-1}+O\left(r^{-\frac{3}{2}}\right)=-2 \Omega \Omega^{-2}+O\left(\Omega^{-3}\right)$

$$
\begin{equation*}
\sigma=O\left(r^{-\frac{3}{2}}\right)=O\left(\Omega^{-3}\right) \tag{6.7}
\end{equation*}
$$

Let
where

$$
\begin{align*}
& \rho=-2 \Omega^{-2}+g \Omega^{-3}  \tag{6.8}\\
& \sigma=h \Omega^{-3}
\end{align*}
$$

$$
g, h,=O(i)
$$

Then using:

$$
D=\frac{\partial}{\partial r}=\Omega^{-i}\left(1+A \cdot \Omega^{-1}-\frac{A^{2}}{2} \Omega^{2}+\frac{A^{3} \Omega^{3}}{2} \ldots \cdot\right) \frac{\partial}{\partial \Omega}
$$

$$
\frac{\partial g}{\partial \Omega}(\Omega+O(1))=-A-g+O\left(\Omega^{-1}\right)
$$

Integrating,

$$
g=\frac{1}{\Omega+O(1)}\left[a+\int \frac{\left(-A+O\left(\Omega^{-1}\right)\right)(\Omega+O(i)) d \Omega}{\Omega+O(1)}\right]
$$

therefore $\quad g=-A+0\left(\frac{\log \Omega}{\Omega}\right)$

For $h$,

$$
\frac{\partial h}{\partial \Omega}(\Omega+O(1))=-h+O\left(\Omega^{-1}\right)
$$

therefore

$$
\begin{equation*}
h=O\left(\Omega^{-1}\right) \tag{6.10}
\end{equation*}
$$

Repeat the process with

$$
\begin{align*}
& \text { Repeat the process with }  \tag{6,12}\\
& \rho_{\text {w }}=-2 \Omega^{-2}-A \Omega^{-3}+g \Omega^{-4} \\
& \sigma=h \Omega^{-4} \\
& g=0(\log \Omega) \\
& h=o(1)  \tag{6,13}\\
& \frac{\partial h}{\partial \Omega}\left(\Omega+o(1)=o\left(\Omega^{-1}\right)\right. \\
& h=\sigma^{0}\left(u, x^{c}\right)+o\left(\Omega^{-1}\right)  \tag{6.14}\\
& \frac{\partial g}{\partial \Omega}(-\Omega+o(1))=o\left(\Omega^{-1} \log \Omega\right) \\
& g=\rho^{0}\left(u, x^{l}\right)+O\left(\Omega^{-1} \log \Omega\right)
\end{align*}
$$

Unlike Newman and Uni, we cannot make $\rho^{0}$ zero by the transformation $q^{\prime}=q-\rho^{0} \quad$, since this would alter the boundary condition $\Lambda=\frac{A^{\text {since }}}{4 \Omega^{3}}+\frac{\Lambda^{\circ}}{\Omega^{7}}$ Continuing the above process we derive:

$$
\begin{align*}
& \rho=-2 \Omega^{-2}-A \Omega^{-3}+\rho^{0} \Omega^{-4}+\left(\frac{1}{2} A^{2}-2 A \rho^{0}\right) \Omega^{-5} \\
& \left.+\left(-\frac{5}{4} A^{4}+4 A^{2} \rho^{0}-\rho^{0^{2}} \frac{-\sigma^{0} \bar{\sigma}^{0}}{2}\right) \Omega^{-6}+O \Omega^{-7}\right)  \tag{6.15}\\
& \sigma^{0}=\sigma^{0} \Omega^{-4}-\left(2 A \sigma^{0}+\psi_{0}^{0}\right) \Omega^{-5}+\ldots \tag{6.16}
\end{align*}
$$

To determine the asymptotic behaviour of $\psi_{1}, \alpha, \beta, \xi^{2}$ and $\omega$ we use the lemma proved by Newman and Penrose: The $n \times n$ matrixßand the column vector $b$ are given functions of $x$ such that:

$$
\begin{equation*}
B=O\left(x^{-2}\right), \quad b=O\left(x^{-2}\right) \tag{6.17}
\end{equation*}
$$

The $n \times n$ matrix $A$ is independent of $x$ and has no eigenvalue with positive real part. Any eigenvalue with vanishing real part is regular. Then all solutions of:

$$
\begin{equation*}
\frac{\partial}{\partial x} y=\left(A x^{-1}+B\right) y+b \tag{6.18}
\end{equation*}
$$

are bounded as $x \rightarrow \infty$

- $y$ is a column
vector.
Hor reason s to be explained below, we will assume for
the moment that

$$
\begin{aligned}
& \phi_{01}=o\left(\Omega^{-5}\right) \\
& \frac{\partial}{\partial \Omega} \phi_{01}=0\left(\Omega^{-6}\right) \\
& \frac{\partial}{\partial x^{L}} \frac{\partial}{\partial x^{j}} \cdots \phi_{01}=o\left(\Omega^{-5}\right)
\end{aligned}
$$

We take as $y$ the column vector

$$
\left[\Omega^{5} \psi_{1}, \Omega^{2} A, \Omega^{2} \bar{A}, \Omega^{2} \beta, \Omega^{2} e^{3}, \Omega^{2} \bar{\xi}^{3}, \Omega^{2} \xi^{4}, \Omega \xi^{4} \omega, \bar{\omega}\right]
$$

$$
\begin{aligned}
& \text { By equations } 3.51,3.13,3.14,3.43,3.44 \\
& A=\left|\begin{array}{ccccccccccc}
-3 & 0 & 6 A & 6 A & 0 & 0 & 0 & 0 & 0 & \text { 5.A } & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & & & & & & & & & 0 \\
0 & & & & & & & & 0 \\
0 & & & & & & & & & 0 \\
0 & & & & & & & & & 0 \\
0 & & & & & & & & 0 \\
0 & & & & & & & & & & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & -1 & 0 & 0 & 0 & 0 & 0 & -2 & 0 \\
0 & -1 & 0 & 0 & -10 & 0 & 0 & 0 & 0 & -2
\end{array}\right|
\end{aligned}
$$

$B$ and $b$ are $o\left(\Omega^{-1}\right)$ expressions involving

$$
\rho, \sigma, \psi_{0}, \frac{\partial}{\partial \Omega} \psi_{0}, \frac{\partial}{\partial x} \psi_{0}, \phi_{01} \quad \text { and } \frac{\partial}{\partial \Omega} \phi_{01}
$$

Thus $\psi_{1}=O\left(\Omega^{-5}\right)$

$$
\begin{aligned}
\alpha, \beta, \xi^{3}, \xi^{4} & =O\left(\Omega^{-2}\right) \\
\omega & =O(1)
\end{aligned}
$$

vince

$$
\begin{aligned}
& \tau=\bar{\alpha}+\beta \\
& \tau=o\left(\Omega^{-2}\right)
\end{aligned}
$$

Using this we integrate equation $(3,12)$ by the same method as above. We obtain

$$
\tau=\tau^{0}\left(u, x^{i}\right) \Omega^{-2}+O\left(\Omega^{-3}\right)
$$

We may make a null rotation of the tetrad on each null geodesic $L_{\mu}^{\prime}=L \mu$

$$
\begin{align*}
& L_{\mu}=L_{\mu}  \tag{b.24}\\
& n^{\prime} \mu=n_{\mu}+a \bar{n}_{\mu}+\bar{a} m_{\mu}+a \bar{a} l \mu \\
& m^{\prime} \mu=M_{\mu}+a L_{\mu}
\end{align*}
$$

a is constant alone the geodesic since the tetrad is parallelly transported.

$$
\text { By taking } a=-\frac{1}{2} \tau^{0} \quad \text { we may make } \tau^{10}=0
$$

Under a null rotation

$$
\phi_{01}^{1}=\phi_{01}+a \phi_{00}
$$

Thus until we have specified the null rotation we cannot impose a boundary condition on $\phi_{0}$, more severe than $\phi_{01}=0\left(\Omega^{-5}\right)$. We will specify the null rotation by $\tau^{0}=0$ and in that tetrad system will impose the boundary condition that $\phi_{0,}=O\left(\Omega^{-7}\right)$ and is uniformly smooth.

Then by using this condition on $\phi_{0,}$ and $\tau=O\left(\Omega^{-3}\right)$, by equation $(3.44)$

$$
\omega=O\left(\Omega^{-1}\right)
$$

$\begin{aligned} \text { using this in equation } & (3.5 i) \\ \psi_{i} & =O\left(\Omega^{-6}\right)\end{aligned}$
then by equation
(3.12)

$$
\tau=o\left(\Omega^{-4}\right)
$$

putting this back in equation (3.44)

$$
\omega=o\left(\Omega^{-2} \log \Omega\right)
$$

by equation (3.5A)

$$
\psi_{1}=o\left(\Omega^{-7} \log \Omega\right)
$$

by equation (3.12)

$$
\tau=O\left(\Omega^{-5} \log \Omega\right)
$$

by equation (3.44)

$$
\omega=\omega^{0} \Omega^{-2}+0\left(\Omega^{-3} \log \Omega\right)
$$

by equation (3.51)

$$
\begin{equation*}
\psi_{1}=O\left(\Omega^{-7}\right) \tag{6.25}
\end{equation*}
$$

by equation ( 3,12 )
by equation (3.44)

$$
\begin{equation*}
\omega=\omega^{0} \Omega^{-2}+O\left(\Omega^{-3}\right) \tag{6.26}
\end{equation*}
$$

By differentiating the equations used with respect to $x^{i}$ one may show that $\psi_{1}, \alpha, \beta, \tau, \xi L, \omega$ uniformly smooth.
Adding equations 3.53 and 3.60 :-

$$
\begin{align*}
\bar{\delta} \psi_{1}-D \psi_{2}+D \phi_{11}-\delta \phi_{01}+D \Lambda_{1} & =\lambda \psi_{0}-3 \rho \psi_{2}+2 \alpha \psi_{1}-\mu \phi_{00}-2 \bar{\alpha} \phi_{0} \\
& +2 \rho \phi_{11}+\sigma \phi_{20} \tag{6.28}
\end{align*}
$$

we may use the lemma again with $y$

$$
y=\left[\begin{array}{ll}
\Omega^{4} & \psi^{2} \\
\Omega^{2} & \lambda^{2} \\
\Omega & \mu
\end{array}\right]
$$

By equations $3.16 ; 3.17 ; 6.28$.

$$
\begin{gathered}
A=\left[\begin{array}{ccc}
-2 & 0 & 3 A \\
0 & 0 & 0 \\
0 & 0 & -1
\end{array}\right] \\
0\left(\Omega^{-2}\right)
\end{gathered}
$$

Therefore

$$
\begin{align*}
& \psi_{12}=o\left(\Omega^{-4}\right) \\
& \lambda=O\left(\Omega^{-2}\right)  \tag{6.29}\\
& \mu=O\left(\Omega^{-1}\right)
\end{align*}
$$

and are uniformly smooth
From $(6.29)$ and $(3.17)$, we may show

$$
\mu=\frac{A}{2} \Omega^{-1}+O\left(\Omega^{-2} \log \Omega\right)
$$

using this in (6.28)

$$
\psi_{2}=O\left(\Omega^{-5} \log \Omega\right)
$$

then by (3.17)

$$
\mu=\frac{A}{2} \Omega^{-1}+\mu^{0}\left(u, x^{6}\right) \Omega^{-2} r o\left(\Omega^{-3} \log \Omega\right)
$$

and $\psi_{2}=O\left(\Omega^{-5}\right)$

Integrating the radial equations $3.13,3.14,3.15,3.16,3.43,3.45$

$$
\begin{align*}
& \text { 3. } 46 \text {. } \\
& \alpha=\alpha^{0} \Omega^{-2}-A \alpha^{0} \Omega^{-3}+\frac{1}{2}\left(3 A^{2} \alpha^{0}-\rho^{0} \alpha^{0}+\bar{\alpha}^{0} 6^{-0}\right) \Omega^{-4}+0\left(\Omega^{-5}\right)(6.3) \\
& \beta=\beta^{0} \Omega^{-2}-A \beta^{0} \Omega^{-3}+\frac{1}{2}\left(3 A^{2} \beta^{0}-\rho^{0} \beta^{0} \gamma \bar{\beta}^{0} G^{0}\right) \Omega^{-4} O\left(\Omega^{-5}\right)(6,3 ? \\
& \gamma=\gamma^{0}-\frac{A}{2} \Omega^{-1}+\frac{A^{2}}{4} \Omega^{-2}+O\left(\Omega^{-3}\right)  \tag{6,33}\\
& \lambda=\lambda^{0} \Omega^{-2}-A\left(\lambda^{0}+\frac{\bar{\sigma}^{0}}{2}\right) \Omega^{-3}+O\left(\Omega^{-4}\right)  \tag{6.34}\\
& \xi^{c}=\xi^{10} \Omega^{-2}-A \Omega^{3} \xi^{c o}+\frac{1}{2}\left(3 A^{2} \xi^{\omega}-\rho^{0} \xi^{L 0}-\xi^{L 0} \sigma^{0}\right) \Omega^{-4}+O\left(\Omega^{-5}\right)\left(\varepsilon^{3}\right. \\
& X^{2}=X^{10}+O\left(\Omega^{-5}\right) \\
& U=-\frac{1}{2}\left(\gamma^{0}+\gamma^{0}\right) \Omega^{2}+A\left(1+\gamma^{0}+\gamma^{0}\right) \Omega-\frac{3}{2} A^{2} \\
& x\left(1+\gamma^{0}+\bar{\gamma}^{0}\right) \log \Omega+\cup^{0}+O\left(\Omega^{-1}\right) \tag{6.37}
\end{align*}
$$

Adding equation $(3.55)+2 \times(\overline{3.59})$

$$
\begin{aligned}
& \delta \psi_{2}-D \psi_{3}+D \phi_{21}-\delta \phi_{20}+2 \overline{\bar{\delta}} \cap=2 \lambda \psi_{1}-2 \rho \psi_{3} \\
& -\frac{i}{3}(\bar{\mu}+2 \mu) \phi_{10}+2(\beta-\bar{\alpha}) \phi_{20}+2 \rho \phi_{21}
\end{aligned}
$$

Therefore

$$
\begin{equation*}
\psi_{3}=\psi_{3}^{0} \Omega^{-4}+O\left(\Omega^{-5}\right) \tag{6,39}
\end{equation*}
$$

By equation $(3.18)$

$$
\begin{equation*}
v=v^{0}-\frac{1}{2} \psi_{3}^{0} \Omega^{-2} r o\left(\Omega^{-3}\right) \tag{6.40}
\end{equation*}
$$

By the orthonormality relations (2.2).

$$
\begin{align*}
& g^{2 i}=x^{c}-\left(\xi^{i} \bar{\omega}+\bar{\xi}^{c} \omega\right) \\
& =X^{20}+O\left(\Omega^{-4}\right) \\
& g^{j g}=-\left(\xi^{L} \xi^{j t}+\xi^{-j j}\right) \quad \quad i, j=3,4 \\
& =-\left(\xi^{i o} \xi^{-} \delta^{0}+\xi^{j o} \xi^{j 0}\right)\left(\Omega^{-\underline{-}} 2 A \Omega^{-5}\right)+O\left(\Omega^{-6}\right) \tag{6.41}
\end{align*}
$$

By making the coordinate transformation

$$
\begin{aligned}
& u^{\prime}=u \\
& r^{\prime}=r \\
& x^{\prime i}=x^{i}+C^{i}\left(u, x^{i}\right)
\end{aligned}
$$

where

$$
\begin{align*}
& C_{11}^{3}=-X^{30}\left(1+C_{33}^{3}\right)-X^{40} C_{34}^{3} \\
& C_{11}^{4}=-X^{40}\left(1+C_{34}^{4}\right)-X^{30} C_{13}^{4} \tag{6.42}
\end{align*}
$$

$X^{10}=0$

$$
x^{i}=D^{i}(x j)
$$

We may use this to reduce the leading term of $g^{i j(i, \gamma=3,4)}$ to a conformally flat metric (c.f. Newman and Unti), that is:

$$
\begin{aligned}
& \text { informally flat metric (c.f. Newman and Unti), that is: } \\
& \left.9^{i j}=-2 P \bar{\rho} \delta^{-i j}\left(\Omega^{-4}-2 A \Omega^{-5}\right)+d \Omega^{-6}\right) \quad(6.43)
\end{aligned}
$$

where

$$
\xi^{30}=-i \xi^{40}=P\left(u, x^{i}\right)
$$

7. Non-radial Equations

By comparing coefficients of the various powers of $\Omega$ in the non-radial equations of $\delta 3$, relations between the integration constants of the radial equations may be obtained:

In equation 3.23 the term in $\Omega^{-1}$ is

$$
-\frac{3}{4} A\left(x^{0}+x^{0}\right)-\frac{3}{4} A
$$

therefore

$$
\begin{equation*}
x^{0}+x^{0}=-1 \tag{71}
\end{equation*}
$$

therefore by $(6.37)$

$$
\begin{equation*}
U=\frac{1}{2} \Omega^{2}+ن()^{2}+0\left(\Omega^{-1}\right) \tag{7.2}
\end{equation*}
$$

In equation $(3.50)$, the constant term is

$$
\nabla^{=}
$$

therefore

$$
\begin{equation*}
V^{0}=0 \tag{7.3}
\end{equation*}
$$

By the $2^{-2}$ term in $(3.47)$

$$
P-P_{j i}=\left(\frac{1}{\gamma^{0}}-\gamma^{0}\right) P
$$

By the $\sqrt[3]{ } 3$ term

$$
P-P_{i i}=0
$$

therefore

$$
\begin{equation*}
y_{0}=y^{0}=-\frac{1}{2} \tag{7.6}
\end{equation*}
$$

$$
\begin{gathered}
P=S\left(x^{l}\right) e^{u} \\
\text { if } \quad S=|S| e^{L \phi}
\end{gathered}
$$

By making a spatial rotation of the tetrad

$$
m^{\prime \mu}=e^{-L \phi} m^{\mu}
$$

we make $S$ real. We take $S=\frac{1}{\sqrt{2}}\left(1+\frac{1}{4}\left(x^{\frac{7}{3}}+x^{x^{2}}\right)\right\}$, the stereographic project factor for a 2 -sphere.
By the $\Omega^{-4}$ term in equation $(3.48)$

$$
\begin{align*}
& \alpha^{0}=\frac{1}{2} \bar{\nabla} S e^{u} \\
& \beta^{0}=-\frac{1}{2} \nabla S e^{u} \\
& \nabla=\frac{\partial}{\partial x^{3}}+c \frac{\partial}{\partial x^{4}} \\
& \text { where } \\
& \text { By the } \Omega^{-4} \text { term in }(3.21) \\
& \frac{1}{2} e^{2 u}(S \nabla \bar{\nabla} S+S \bar{\nabla} \nabla S)=-2 \mu^{0}-\frac{A^{2}}{2}+(\nabla P)(\bar{\nabla} P) \\
& \mu^{0}=-\frac{A^{2}}{4}-\frac{S^{2}}{2} \nabla \bar{\nabla} \log S e^{2 u} \\
&=-\frac{A^{2}}{4}\left[1+e^{2 u}\right]  \tag{7.6}\\
&(3.59)(3.60)(3.61) \\
& \frac{\partial}{\partial u} \phi_{01}=O\left(\Omega^{-7}\right)
\end{align*}
$$

$$
\begin{align*}
& \frac{\partial}{\partial u} \phi_{00}=O\left(\Omega^{-7}\right) \\
& \frac{\partial}{\partial u} \Lambda=H \Omega^{-5}+O\left(\Omega^{-6} \log \Omega\right) \tag{7.7}
\end{align*}
$$

where

$$
H=-\frac{A^{2}}{8}+\frac{3 U^{0}}{4}+\frac{\rho^{0}}{4}+\frac{A^{2} e^{2 u}}{8}
$$

By making a coordinate transformation*

$$
\begin{align*}
& y^{\prime}=4-\int_{u 0}^{4} H d u^{\prime \prime} \\
& H^{\prime}=0 \\
& U^{0}=\frac{A^{2}}{6}-\frac{A^{2} e^{2 u}}{6}-\frac{\rho^{0}}{3} \\
& \text { By therefore } \Omega^{-4} \text { term in }(3.26) \\
& \rho_{0 i}^{0}-\rho^{0}+4 U^{0}=-\frac{A^{2}}{2}\left(i+e^{2 u}\right)  \tag{7.9}\\
& \text { therefore } \quad \rho_{\mu 1}^{0}-\frac{7}{3} \rho^{0}+\frac{7}{6} A^{2}-\frac{1}{6} A^{2} e^{2 u}=0 \\
& \rho^{0}=\frac{A^{2}}{2}\left(1-e^{2 u}\right)+C\left(x^{i}\right) e^{\frac{7}{3} u} \tag{7.10}
\end{align*}
$$

*This transformation does not upset the boundary conditions on the hypersurface $u=u^{0}$
$\qquad$

$$
\begin{align*}
& \text { By the } \Omega^{-4} \text { term in }(3.25) \\
& \lambda^{0}=\frac{1}{2}\left(\bar{\sigma}_{, 1}^{0}-\bar{\sigma}^{0}\right)  \tag{7,i1}\\
& \text { By the } \Omega^{-4} \text { term in }(3.22) \\
& \psi_{3}^{0}=\left(\bar{\sigma}_{, 1}^{0}-\bar{\sigma}^{0}\right) e^{u} \nabla S-\frac{1}{2} e^{u} S \nabla\left(\bar{\sigma}_{j 1}^{0}-\bar{\sigma}^{0}\right)(7,12) \\
& \text { By the } \Omega^{-2} \text { term in (3.50) } \\
& 2 \omega^{\circ}-\omega_{1}^{0}=\frac{1}{2} \bar{\psi}_{3}^{0} \\
& \omega^{0}=\frac{e^{u}}{4}\left(S \bar{\nabla} \sigma^{0}-2 \sigma^{0} \bar{\nabla} S\right)+K\left(x^{2}\right) e^{2 u}  \tag{713}\\
& \text { By the } \Omega^{-6} \text { term in (3.20) } \\
& e^{u} S \nabla \rho^{0}+4 \omega^{\circ}-e^{u} S \bar{\nabla} 6^{\circ}=-2 \sigma^{\circ} \bar{\nabla} S e^{u} \\
& \text { therefore } \quad C=k=0  \tag{714}\\
& \text { therefore } U^{0}=0  \tag{7.16}\\
& \rho^{0}=\frac{A^{2}}{2}\left(1-e^{2 u}\right) \tag{7.15}
\end{align*}
$$

Using $(7.6),(7.16)$, in $(6.28)$

$$
\psi_{2}=O\left(\Omega^{-6} \log \Omega\right)
$$

Then by $(3.17)$

$$
\begin{align*}
(3.17) & \frac{A}{2} \Omega^{-1}-\frac{A^{2}}{4}\left(1+e^{2 u}\right) \Omega^{-2}+\frac{A^{3}}{2}\left(\frac{1}{2}+e^{24}\right) \Omega^{-3} \\
& +O\left(\Omega^{-4} \log \Omega\right) \tag{7.17}
\end{align*}
$$

Using this in (6.28)

$$
\psi_{2}=O\left(\Omega^{-6}\right)
$$

$$
\text { By } \begin{align*}
(3.51) \cdot(3.59) & (3.60)(3.61) \\
\frac{\partial}{\partial u} \phi_{01} & =0\left(\Omega^{-7}\right) \\
\frac{\partial}{\partial u} \phi_{00} & =0\left(\Omega^{-9}\right) \\
\frac{\partial}{\partial u} \wedge & =0\left(\Omega^{-7}\right) \\
\frac{\partial}{\partial u} \psi_{0} & =0\left(\Omega^{-7}\right) \tag{7.19}
\end{align*}
$$

Therefore if the boundary conditions $(5.1-4)$ hold on one null hypersurface, they will hold on succeeding hypersurfaces.
By $(3,57)$

$$
\psi_{4}=O\left(\Omega^{-2}\right)
$$

The "peeling off" behaviour is therefore:

$$
\begin{aligned}
& \psi_{4}=O\left(T^{-1}\right) \\
& \psi_{3}=O\left(T^{-2}\right) \\
& \psi_{2}=O\left(T^{-3}\right) \\
& \psi_{1}=O\left(r^{-\frac{7}{2}}\right) \\
& \psi_{0}=O\left(T^{-\frac{7}{2}}\right)
\end{aligned}
$$

As mentioned before, this asymptotic behaviour is independent of the zero of $r$ and will hold for any affine parameter

To perform the remaining integrations we will assume
for definiteness:

$$
\begin{align*}
& \text { definiteness: }  \tag{7.22}\\
& \phi_{01}=\phi_{0}^{0} \Omega^{-7}+\phi_{0 i}^{1} \Omega^{-8}+O\left(\Omega^{-9}\right) \\
& \psi_{0}=\psi_{0}^{0} \Omega^{-7}+\psi_{0}^{1} \Omega^{-8}+o\left(\Omega^{-4}\right) \\
& \Lambda=\frac{\theta}{} \Omega^{-3}+\Lambda_{0}^{0} \Omega^{-7}+o\left(\Omega^{-8}\right) \\
& \phi_{00}=3 A \Omega^{-5}+\phi_{00}^{0} \Omega^{-9}+o\left(\Omega^{-10}\right)
\end{align*}
$$

Then:

$$
\text { n: } \begin{align*}
\rho & =-2 \Omega^{-2}-A \Omega^{-3}+A^{2}\left(1-e^{2 u}\right) \Omega^{-4}-\frac{A^{3}}{2}\left(1-2 e^{2 u}\right) \Omega^{-5} \\
& +\left[A^{4}\left(\frac{5}{8}-\frac{7}{8} e^{2 u}-\frac{1}{8} e^{i u}\right)-\frac{\sigma^{0} 0^{0}}{2}\right] \Omega^{-6} \\
& +\frac{1}{3}\left[A^{5}\left(-\frac{37}{8}+8 e^{2 u}+8 e^{2 u}+2 e^{4 u}\right)-\phi_{00}^{0}\right. \\
& \left.+\sigma^{0}\left(3 A \sigma^{0}+\psi_{0}^{0}\right)+\sigma^{0}\left(3 A \bar{\sigma}^{0}+\psi_{0}^{0}\right)\right] \Omega^{-5} \\
& +0\left(\Omega^{-8}\right)  \tag{7.23}\\
\sigma & =\sigma^{0} \Omega^{-4} .\left(2 A 5^{0}+\psi_{0}^{0}\right) \Omega^{-5}+O\left(\Omega^{-6}\right)(7.23) \\
\tau & =-\frac{1}{3}\left(\phi_{0:}^{0}+\psi_{1}^{0}\right) \Omega^{-5}+0\left(\Omega^{-6} \log \Omega_{0}\right)(7.26)
\end{align*}
$$

$$
\begin{align*}
& \omega=\frac{e^{u}}{4}\left(S \bar{\nabla} \sigma^{\circ}-2 \sigma^{\circ} \bar{\nabla} S\right) \Omega^{-2}-\left[\frac{A e^{u}}{4}\left(S \bar{\nabla} \sigma^{\circ}-2 \sigma^{\circ} \bar{\nabla} S\right)\right. \\
& \left.+\frac{1}{3}\left(\phi_{0 i}^{0}+\psi_{i}^{0}\right)\right] \Omega^{-3}+O\left(\Omega^{-4} \log \Omega\right)  \tag{7.26}\\
& \gamma=-\frac{1}{2}-\frac{A}{2} \Omega^{-1}+\frac{A^{2}}{4} \Omega^{-2}-\frac{A^{3}}{4} \Omega^{-3}+\frac{1}{4}\left(\frac{5}{4} A^{4}-\psi_{2}^{0}\right) \Omega^{-4} \\
& +O\left(\Omega^{-5}\right) \\
& \text { (7.27) } \\
& \mu=\frac{A}{2} \Omega^{-i}-\frac{A^{2}}{4}\left(1+e^{2 u}\right) \Omega^{-2}+\frac{A^{3}}{4}\left(1+2 e^{2 u}\right) \Omega^{-3} \\
& -\frac{1}{2}\left[A^{4}\left(\frac{5}{8}+\frac{7}{4} e^{2 u}+\frac{1}{8} e^{4 u}\right)_{4}^{4} \frac{\sigma^{0}}{2}\left(\bar{\sigma}_{31}^{0}-\bar{\sigma}^{0}\right)+\psi_{5}^{0}\right] \\
& \times \Omega^{-4}+O\left(\Omega^{-5}\right) \\
& \text { (7.28) } \\
& \lambda=\frac{1}{2}\left(\bar{\sigma}_{i 1}^{0}-\bar{\sigma}_{0}^{0}\right) \Omega^{-2}-\frac{A \bar{\sigma}_{i,}}{2} \Omega^{-3}+o\left(\Omega^{-4}\right) \quad(7.29) \\
& V=-\frac{1}{2}\left(\left(\bar{\sigma}_{i}^{0}-\bar{\sigma}^{0}\right) e^{u} \nabla S-\frac{1}{2} e^{u} S \nabla\left(\bar{\sigma}_{i}^{0}-\bar{\sigma}^{0}\right)\right) \Omega^{-2} \\
& +O\left(\Omega^{-3}\right) \\
& \alpha=\frac{1}{2} e^{u} \bar{\nabla} S \Omega^{-2}-\frac{1}{2} A e^{u} \bar{\nabla} S \Omega^{-3} \\
& +\frac{1}{4}\left[A^{2} e^{u} \nabla S\left(\frac{5}{2}+\frac{1}{2} e^{u}\right)+e^{4}(\nabla S) \bar{\sigma}^{0}\right] \Omega^{-4} \\
& \text { To( } \left.\Omega^{-5}\right)
\end{align*}
$$

$$
\begin{align*}
& \xi^{3}=e^{u} S \Omega^{-2}-A e^{u} S \Omega^{-3}+\frac{1}{2}\left[A^{2} e^{u} S\left(\frac{5}{2}+\frac{1}{2} e^{u}\right)\right. \\
& \left.-e^{4} S \sigma^{-0}\right) \Omega^{-4}+O\left(\Omega^{-5}\right) \\
& U=\frac{1}{2} \Omega^{2}-\frac{1}{8}\left(\psi_{2}^{0}+\psi_{2}^{0}\right) \Omega^{-2}+O\left(\Omega^{-3}\right) \quad(7.33) \\
& X^{3}=\frac{e^{u} S}{15}\left[\phi_{0 i}^{0}+\bar{\phi}_{0}^{0}+\psi_{1}^{0}+\bar{\psi}_{1}^{0}\right] \Omega^{-5}+O\left(\Omega^{-6} \log \Omega\right) \\
& \text { (736) } \\
& \psi_{u}^{0}=\left[-\bar{\sigma}^{0}+\frac{3}{2} \sigma_{21}^{0}+-\frac{1}{2} \sigma_{j i 1}^{0}\right] \Omega_{r}^{-2}+\left[-\frac{\sigma^{0}}{2}-\frac{3}{4} \bar{\sigma}_{11}^{0}\right. \\
& \left.+\frac{1}{2} \bar{\sigma}_{, 11}^{0}\right] \Omega^{-3}+\left[A^{2}\left(\bar{\sigma}^{0}+\frac{3}{4} \bar{\sigma}_{21}^{0}-\frac{3}{8} \bar{\sigma}_{211}^{0}\right)\right. \\
& +\frac{A^{2}}{4}\left(-\bar{\sigma}^{0}+\frac{3}{2} \bar{\sigma}_{j 1}^{0}-\frac{1}{2} \bar{\sigma}_{\prime \prime}^{0}\right) e^{2 u}-e^{2 u \bar{\nabla}}(\rho \\
& \left.x\left(\bar{\sigma}_{11}^{0}-\bar{\sigma}^{0}\right)^{\frac{3}{2}} \nabla\left(S\left(\bar{\sigma}_{1}^{0}-\bar{\sigma}^{0}\right)^{\frac{1}{2}}\right)\right) \\
& \left.+\frac{3 A}{8} \Psi_{0}^{0}\right] \Omega^{-4}+O\left(\Omega^{-5}\right)  \tag{7.35}\\
& \psi^{3}=\left[e^{u}\left(\bar{\sigma}_{j 1}^{0}-\bar{\sigma}^{\dot{0}}\right) \nabla S-e^{u} S \nabla\left(\bar{\sigma}_{j 1}^{0}-\bar{\sigma}^{0}\right)\right] \Omega^{-4} \\
& +\left[A e^{u}\left(-2\left(\bar{\sigma}_{, 1}^{0}-\frac{11}{8} \bar{\sigma}^{0}\right) \nabla S-S \nabla\left(\bar{\sigma}_{, 1}^{0}-\frac{11}{8} \bar{\sigma}^{0}\right)\right)\right. \\
& \left.+\frac{1}{2} \bar{\phi}_{0 i}^{0}\right] \Omega^{-5}+O\left(\Omega^{-6}\right) \tag{7.36}
\end{align*}
$$

$$
\begin{align*}
\psi_{2}= & \psi_{2}^{0} \Omega^{-6}+\left[-\frac{3}{2} A \psi_{2}^{0}-e^{4} S^{2} \bar{\nabla}\left(\frac{\psi_{1}^{0}}{S}-\phi_{01}^{0}\right)\right. \\
& +\frac{1}{2} \psi_{0}^{0}\left(\bar{\sigma}_{11}^{0}-\bar{\sigma}^{0}\right)+\frac{3 A}{4} \sigma^{0} \bar{\sigma}_{11}^{0}-\frac{3 A}{2} \sigma^{0} \sigma^{-0} \\
& \left.+16 \Lambda^{0}\right] \Omega^{-7}+\theta\left(\Omega^{-8} \log \Omega\right) \tag{7.37}
\end{align*}
$$

where:

$$
\begin{aligned}
\Psi_{2}^{0}-\bar{\psi}_{2}^{0} & =\left[e ^ { 2 u } \left(\frac{S^{2}}{2} \bar{\nabla} \bar{\nabla} \sigma^{0}-S(\bar{\nabla} S)\left(\bar{\nabla} \sigma^{0}\right)\right.\right. \\
& \left.\left.+\sigma^{0}(\bar{\nabla} S)^{2}-\sigma^{\circ} S \bar{\nabla} \bar{\nabla} S\right)-\frac{1}{2} \sigma^{\circ} \bar{\sigma}_{n}^{0}\right]-c \cdot c
\end{aligned}
$$

$\psi_{2}^{0}+\bar{\psi}_{2}^{0}$ is undetermined (7.38)

$$
\psi_{1}=\psi_{1}^{0} \Omega^{-7}+\psi_{1}^{1} \Omega^{-8} \log \Omega+\psi_{1}^{2} \Omega^{-8}+O\left(\Omega^{-9} \log \Omega\right)
$$

where

$$
\begin{align*}
\psi_{1}^{0}= & e^{u}\left[S \bar{\nabla}\left(\psi_{0}^{0}+\frac{15}{4} \sigma^{0}\right)-\left(2 \psi_{0}^{0}+\frac{15}{2} \sigma^{0}\right) \bar{\nabla} S\right] \\
& -3 \phi_{01}^{0}  \tag{7.39}\\
\psi_{1}^{\prime}= & -e^{u}(S \bar{\nabla}-2 \bar{\nabla} S)\left(5 A \psi_{0}^{0}-\psi_{0}^{1}+15 A \sigma^{0}\right) \\
& +4 \phi_{0}^{\prime}
\end{align*}
$$

$\psi_{1}^{2}$ is undetermined
By (3.54)

$$
\begin{equation*}
\psi_{i, 1}^{i}=3 \psi_{i}^{1} \tag{7.41}
\end{equation*}
$$

Thus the $u$ derivative of $\psi_{1}^{i}$, depends only on itself and not on the radiation field. It therefore represents a type of disturbance unconnected with radiation. If it is zero on one hypersurface, it will remain zero. In this case it is possible to continue the expansions of all quantities in negative powers of $\Omega$ without any log terms appearing.
8. The Asymptotic Group

The metric has the form:

$$
\begin{aligned}
& g^{11}=9^{13}=g^{14}=0, \quad g^{12}=1 \\
& g^{22}=\Omega^{2}+0\left(\Omega^{-2}\right) \\
& g^{2 i}=0\left(\Omega^{-4}\right) \\
& g^{i j}=-2 p^{9} \cdot \delta^{i j} \Omega^{-4}+2 A p^{2} \delta^{i} \Omega^{-5}+0\left(\Omega^{-6}\right)
\end{aligned}
$$

The asymptotic group is the group of coordinate transformations that leave the form of the metric and of the boundary conditions unchanged. It can be derived most simply by considering the corresponding infinitesimal transformations:

$$
x^{\prime \mu}=x^{\mu}+\varepsilon^{\mu}\left(x^{v}\right)
$$

Then

$$
\begin{array}{rlr}
\bar{\delta}^{\mu v} & =g^{\prime \mu v}(x)-g^{\mu v}(x) & \\
& =\epsilon\left(g^{\mu \alpha} k_{j a}^{v}+g^{\alpha v} k_{j \alpha}^{\mu}-g_{j \alpha}^{\mu v} k^{\alpha}\right)(\underline{(\delta \cdot 2)} \\
\bar{\delta} \Lambda & =-\varepsilon n_{, \alpha} k^{\alpha} \\
\bar{\delta} \phi_{00} & =\epsilon R_{i \alpha} k_{j i}^{\alpha}+\frac{1}{2} \in R_{1, \alpha} k^{\alpha} & (8 \cdot 4) \\
\bar{\delta} \phi_{01} & =\frac{1}{2} \varepsilon\left(R_{i \alpha} k_{33}^{\alpha}+R_{3 \alpha} \pi_{j,}^{\alpha}+R_{13, \alpha} k^{\alpha}\right)(8 \cdot 5)
\end{array}
$$

To obtain the asymptotic group we demand

$$
\begin{aligned}
& \bar{\delta}_{g}^{"}=\dot{\delta}_{g}^{\prime 2}=\bar{\delta}^{i 3} g^{22}=\bar{\delta}_{g}^{14}=0 \\
& \delta_{g}^{22}=0\left(\Omega^{-2}\right)^{2} \\
& \bar{\delta}_{g}^{2 i}=0\left(\Omega^{-4}\right) \\
& \bar{\delta}^{i j}=0\left(\Omega^{-6}\right) \\
& \bar{\delta} \Lambda=0\left(\Omega^{-7}\right) \\
& \bar{\delta} \phi_{00}=o\left(\Omega^{-9}\right) \\
& \bar{\delta} \phi_{01}=o\left(\Omega^{-7}\right)
\end{aligned}
$$

${ }^{B y} \quad \bar{\delta}_{g}^{\prime \prime}=0$,

$$
K^{i}=K^{01}\left(u, x^{i}\right)
$$

$$
\begin{equation*}
\therefore \kappa^{0.3}{\underset{j 3}{4}}^{4}=K^{04_{4}^{13}} \tag{8.13}
\end{equation*}
$$

$$
\begin{equation*}
2 S K_{33}^{03}-S_{13} \hbar^{03}-S_{14} K^{04}-2 S K^{1}=0 \tag{8.16}
\end{equation*}
$$

12) and ( $(8.13)$ imply that $K^{\circ{ }^{c}}$ is an analytic function of $x^{3}+i x^{4}$. This is a consequence if the fact that we have

$$
\begin{aligned}
& { }_{B y} \bar{\delta} \Lambda=O\left(\Omega^{-7}\right) \\
& k^{2}=O\left(\Omega^{-2}\right) \\
& 8 g^{12}=0=K_{12}^{2}+K_{11}^{1} \operatorname{ig}^{23} K_{j_{3}}+g^{\left(\frac{8.8}{24} K_{1}\right.} \\
& \therefore k_{i, 1}^{\prime 2}=0 \\
& k^{\prime}=K^{01}\left(x^{2}\right) \\
& 8 g^{13}=0=k_{, 2}^{3}+g^{33} k_{j_{3}}^{1}+g^{34} k_{j_{4}}^{1} \\
& \therefore k^{3}=k^{03}\left(u, x^{i}\right)-4 \sigma^{-1} p^{2} k ;{ }_{3}^{\prime}+O\left(\Omega^{-3}\right)(810) \\
& \bar{\delta}_{g}^{23}=O\left(\Omega^{-4}\right)=k_{31}^{3}+2 v k_{11}^{3}+O\left(\Omega^{-4}\right) \\
& \therefore \pi^{03}=\pi^{03}\left(x^{i}\right) \text { ( }(\underline{11}) \\
& \bar{\delta} g^{i j}=g^{i 2} k_{j 2}^{j}+g^{j 2} K_{j 2}^{i}+g^{i k} K_{j k^{j}}^{j} g^{i \pi} \kappa^{i} \\
& -g_{j}^{j}, \pi k^{k} \\
& \therefore K_{{ }_{4}}^{03}=-k_{23}^{04}
\end{aligned}
$$

 form. Thus the only allowed transformations of $x^{6}$ are the conformal transformations of the form:

$$
\begin{array}{r}
x^{3}+i x^{4}=\frac{a\left(x^{3}+c x^{4}\right)+b}{a\left(x^{3}+i x^{4}\right)+d}  \tag{8.15}\\
\\
a d-b c=1
\end{array}
$$

When the six parameters $a, b, c, d$ are given $K^{\prime}$ is uniquely determined by $(8,14) \quad K^{2}$ is also uniquely determined. Thus the asymptotic group is isomorphic to the conformal group in two dimensions. Sachs $(\bar{\varnothing})$ has shown that this is isomorphic to the homogeneous Lorentz group. It is also however isomorpinic to the group of motions of a 3-space of constant negative curvature which is the group of the unperturbed RobertsonWalker space. Thus the asymptotic group is the same as the group of the undisturbed space. It is not enlarged by the presence of radiation. This is interesting because in the case of gravitational radiation in empty, asymptotically flat space, it turns out that the asymptotic group contains not only the 10 dimensional inhomogeneous Lorentz group, the group of motions of flat space, but also infinite dimensional "supertranslations". It has been suggested that these supertranslations might have some physical significance in elementary particle physics. The above result would seem
to indicate that this is probably not the case since our universe is almost certainly not asymptotically flat though it may be asymptotically Robertson-walker.
9. What an observer would measure

The velocity vector $V_{m}$ of an observer moving with the dust will be:

$$
\begin{aligned}
& V=\Omega^{-1}+o\left(\Omega^{-5}\right) \\
& V \\
& V=\frac{-1}{2} \Omega+o\left(\Omega^{-3}\right) \\
& \frac{V}{3}=o\left(\Omega^{-3}\right) \\
& V_{4}=o\left(\Omega^{-3}\right)
\end{aligned}
$$

, the projection of the wave vector $L^{a}$ in the observer's rest-space (the apparent direction of the wave) will be:

$$
\begin{aligned}
& q=\delta_{m}^{2}-V V_{1}^{2} \\
& q=\Omega^{-2}+0\left(\Omega^{-5}\right) \\
& =\frac{-}{2}+O\left(\Omega^{-4}\right)
\end{aligned}
$$

$$
\begin{aligned}
& q=0\left(2^{-4}\right) \\
& Q^{3}
\end{aligned}=0\left(\sqrt{2}^{-4}\right)
$$

The observer's orthonormal tetrad may be completed by two

$$
\left.\begin{array}{l}
\text { space-like unit vectors } \\
S_{i}=0\left(\Omega^{-4}\right) \\
S_{2}=\left(3\left(2^{-2}\right)\right. \\
2
\end{array}\right)
$$

We write $e^{\alpha}=\left(V^{\alpha}, q, s^{a}, t^{\alpha}\right)$

By measuring the relative accelerations of neighbouring dust particles, the observer may determine the 'electric'
components of the gravitational wave:

$$
E_{a b}=-C_{a p b q} v^{?} v^{q}
$$

In the observer's tetrad this has components

$$
\begin{align*}
E & =\left[\begin{array}{ccc}
0 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -1
\end{array}\right] \circ\left(\Omega^{-4}\right)+\left[\begin{array}{lll}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{array}\right] 0\left(\Omega^{-4}\right) \\
& +\left[\begin{array}{ccc}
0 & 1 & 1 \\
1 & 0 & 0 \\
1 & 0 & 0
\end{array}\right] 0\left(\Omega^{-5}\right) T\left[\begin{array}{ccc}
0 & 1 & -1 \\
1 & 0 & 0 \\
-1 & 0 & 0
\end{array}\right] 0\left(\Omega^{-5}\right) \\
& +\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & -\frac{1}{2} & 0 \\
0 & 0 & -\frac{1}{2}
\end{array}\right] 0\left(\Omega^{-6}\right) \tag{9.4}
\end{align*}
$$

This should be compared to the behaviour for asymptotically
flat space for which

$$
\begin{array}{rl}
E & =\left[\begin{array}{lll}
0 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -1
\end{array}\right]^{-1}+\left[\begin{array}{lll}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{array}\right]^{\left(r^{-1}\right)} \\
& {\left[\begin{array}{lll}
0 & 1 & 1 \\

## CHAPITER 4

## Sinsularities

If the Einstein equations without cosmological constant are satisfied, a Robertson-Walker model can 'bounce' or avoid a singularity only if the pressure is less than minus onethird the density. This is clearly not a property possessed by normal matter though it might be possessed by a field of negative energy density like the 'c' field. However there is a grave quantum-mechanical difficulty associated with the existence of negative energy density, for there would be nothing to prevent the creation, in a given volume of spacetime, of an infinite number of quanta of the negative energy field and a corresponding infinity of particles of positive energy. If we therefore exclude such fields, all RobertsonWalker models must be of the 'big-bang' type, that is they have a singularity in the past and maybe one in the future as well. It has been sugsested ${ }^{1}$ that the occurrence of these singularities is a consequence of the high degree of symmetry of the Robertson-Walker models which restricts the expansion and contraction so that they are purely radial and that more realistic models with fewer or no exact symmetries would not have a singularity. This chapter will be devoted

to an examination of this question and it will be shown that provided certain physically reasonable conditions hold, any model must have a singularity, that is, it cannot be a geodesically complete $C^{1}$, piecewise $c^{2}$ manifold.
2. The Fundamental Equation

The expansion $\theta=V^{a} ; a$ of a time-like geodesic congruence with unit tangent vector $V^{a}$ obeys equation (7) of Chapter 2:

$$
\begin{equation*}
\theta_{; a}^{2:} V^{a}=-\frac{1}{3} \theta^{2}-2 \sigma^{2}+2 \omega^{2}-R_{a b} V^{a} V^{b} \tag{1}
\end{equation*}
$$

A point $q$ will be said to be a singular point on a geodesic of a time-like geodesic congruence if $\theta$ for the congruence is infinite on $\gamma$ at $q$. A point $q$ will be said to be conjugate to a point $p$ along a geodesic $\gamma$ if it is a singular point on $\gamma$ of the congruence of all time-like geodesics through $p$. A point $q$ will be said to conjugate to a space-like hypersurface. $H^{3}$ if it is a singular point of the congruence of geodesic normals to $H^{3}$. An alterative description of conjugate points may be given as follows: let $K^{a}$ be a vector connecting points corresponding distances along two neighbouring geodesics in a congruence with unit
tangent vector $V^{a}$. Then $K^{a}$ is 'dragged' along by the congruence, that is

$$
\begin{align*}
& \neq K^{a}=0 \\
\therefore \quad & \frac{D K^{a}}{D S}=V_{a: b} K^{b}  \tag{2}\\
\therefore & \frac{D^{2} K^{a}}{D S^{2}}=R_{b c d}^{a} V^{b} V^{c} K^{d} \tag{3}
\end{align*}
$$

a
Introducing an orthonormal tetrad $e^{e}$ parallelly transported. avon $V^{a}$ with $e^{a}=V^{a}$ we have

$$
\begin{equation*}
\frac{d^{2} K}{d s^{2}}=-a_{m}^{n} K \tag{4}
\end{equation*}
$$

where

$$
a_{m}^{n}=e^{n} e_{m}^{a} R_{a c b d} V^{c} V^{d}
$$

A solution of (4) will be called a Jacobi field. There are clearly eight independent solutions. Since $V^{a}$ and $\xi^{G} V^{a}$ are solutions, the other six independent solutions of ( 4 ) may be taken orthogonal to $V^{a}$. Then $q$ is conjugate to $p$ alone a geodesic $\gamma$ if, and only if, there is a Jacobi field along $\gamma$ which vanishes at $p$ and $q$. This may be shown as follows: the Jacobi fields which vanish at $P$ may be regarded as generating neighbouring geodesics in the irrotational congruence of all time-like geodesics through $p$. Therefore they obey

$$
\frac{d k}{d s}=V_{m i n} k^{n}
$$

They may be written

$$
K_{m}={\left.\underset{m n}{ }(s) \frac{d k^{n}}{d s}\right|_{p}, ~}^{d}
$$

where

$$
\frac{d A}{d s}=V A_{m: r}^{n}
$$

Near $p,{ }_{m n}(S)$ will be positive definite. There will be a Jacobi field vanishing at $p$ and $q$ if, and only if, $\operatorname{det}(A(q)))=0$
But

$$
A(s)=\exp \left(\int_{p=m: n}^{s} V s^{\prime}\right)^{2}
$$

Therefore

$$
\theta=\frac{1}{\operatorname{det}(A)} \frac{d}{d s}(\operatorname{det}(A))
$$

and

$$
\frac{d^{2} A}{d s^{2}}=-a \hat{A}^{r}
$$

Therefore $\frac{d}{d s}(A)$ is finite
Hence $\theta$ is infinite where and only where $\operatorname{det}\binom{A}{m A}=0$. Thus the two definitions of conjugate points are equivalent.

This also shows that singular points of congruences are points where neighbouring geodesics intersect.

For null geodesic congruences with parallelly transported tangent vector ${ }^{a}$ we may define the convergence $\rho$ as in Chapter 3. This obeys

$$
\rho_{, a} C^{a}=\rho^{2}+6 \bar{\sigma}+\frac{1}{2} R_{a b} L^{a} L^{b} \text { (5) }
$$

He define a singular point of a null geodesic congruence as one where $\rho$ is infinite.

The condition that the pressure is greater than minus one-third tide density may be stated more generally as condition (a).

$$
\text { (a) } E>0, \quad E>\frac{1}{2} T \text {, for any }
$$

observer with 4-velocity $\omega^{a}$, where $E=T_{a b} \omega^{a} \omega^{b}$ is the enercy density in the rest-frame of the observer and $T=T^{a} a \quad$ is the rest-mass density.

Condition (a) will be satisfied by a perfect fluid with density $\mu>0$ and pressuce $p>-\frac{1}{3} \mu$. It implies $R_{a b} V^{a} V^{b}>0$ for any time-like or null vector $V^{a}$. Therefore by equations (1) and (5) any time-like or null irrotational geodesic congruence must have a singular point on each geodesic within a finite affine distance. Obviously if the flow-lines form an irrotational geodesic congruence, there will be a physical singularity at the singular points of the congruence where the density and hence the curvature are infinite. This will be the case if the universe is filled with non-rotating dust ${ }^{2,3}$. However, if the flow-lines are not geodesic (ie. non-vanishing pressure gradient) or are rotating, equation (1) cannot be applied directly.
3. Spatially Homogeneous Anisotropic Universes

The Robertson-ivalker models are spatially homogeneous and isotropic, that is, they have a six parameter group of motions transitive on a space-like surface. If we reduce the symmetry by considering models that are spatially homogeneous but anisotropic (thetis, they have a three parameter group of motions transitive on a space-like hypersurface) then the matter flow may have rotation, acceleration and shear. Thus there would seem to be the possibility of non-singular models. L. Shepley ${ }^{4}$ has investigated one particular homogeneous model containing rotating dust and has shown that there is always a singularity. Here a general result will be proved.

There must be a singularity in every model which satisfies condition (a) and,
(b) there exists a Gr of motions on the space or on universal covering space $*, \mu \geqslant 3$ which is transitive on at

* Nee section 5
least one space-like surface but space-time is not stationary, (c) the energy-momentum tensor is that of a perfect fluid,

$$
T_{a b}=(\mu+p) u_{a} U_{b}-9 g_{a b} \cdot U^{a} \text { is the tangent to }
$$ flow-lines and is uniquely defined as the time-like eigenvector of the Ricci tensor.

PROOF
$R$, the curvature scalar must be constant on a spacelike surface of transitivity $H^{3}$ of the group. Wherefore $R_{\text {;a }}$ must be in the direction of the unit time-like normal $V^{a}$ to $\mathrm{H}^{3}$.

$$
V_{a}=\frac{e\left(R_{i a}\right) R_{i a}}{\sqrt{f}}
$$

where $R_{i a} R^{\prime a}=f>0$
$e(R ; a)$ is an indicator $=+1$ if $R ; a$ is past directed

$$
=-1 \text { if } R ; a \text { is future directed }
$$

Then $V_{[a ; b]}=0$.
Thus $V_{a}$ is a congruence of geodesic irrotational time-like vectors. By condition (a), $R_{a b} V^{a} V^{b}>0$

Therefore the congruence must have a singular point on each geodesic (by equation 1) either in the future or in the past. Further, by the homogeneity, the distance along each geodesic from $\mathrm{Ht}^{3}$ to the singular point must be the same for each ceocesic. Thus if the surfaces of transitivity remain space-like, they must degenerate into, at the most, a 2 -surface $\mathrm{C}^{2}$ which will be uniquely defined. Let $M$ be the subset of the flow-lines of the matter which intersect $C^{2}$. Let $L$ be the nonempty subset of $H^{3}$ intersected by $M$. Since there is a group transitive on $H, L$ must be $H^{3}$ itself. Thus all the
flow-lines through $H^{3}$ must intersect the $2-$ surface $C^{2}$. Thus the density will be infinite there an there will be a physical singularity. Alternatively if the surfaces of transitivity do not remain space-like, there must be at least one surface which is null - call this $S^{3}$. At $S^{3}, f=0$, $R_{; a} \neq 0$ (if $R_{; a}$ is zero, we can take any other scalor polynomial in the curvature tensor and its covariant derivatives. They cannot all be zero if space-time is not stationery). We introduce a geodesic irrotational null congruence on $s^{3}$ with tangent vector $L^{a}$ where $l_{a} R_{; a}$. Then by equation (5), there will be a singular point of each null geodesic in $S^{3}$ within finite affine distance either in the future or in the past. The 2-surface of these singular points will be uniguely defined. The same arsument used before shows that the density becomes infinite and there is a physical singularity. In fact as $S^{3}$ is a surface of homoseneity, the whole of $S^{3}$ will be singular and it is not meaningful to call it null or to distinguish this case from the case where the surfaces of transitivity remain space-like.
whe conditions (a), (b), (c) may be weakened in two ways. Condition (b) that there is a group of motions throughout space-time may be replaced by ( $b^{\prime}$ ) and (d).
(b/ Thene is a space-like hypersurface $H^{3}$ in which there are three independent vector fields $x^{a}$ such that
 one homogeneous space section.
(d) There exist equations of state such that the cauchy development of $\mathrm{H}^{3}$ is determinate.

Then succeading space-like surfaces of constant $R$ are homoseneous and much the same proof can be given that there are no non-singular models satisfying $(a),(b),(c)$, (d).

The only property of perfect fluids that has been used in the above proof is that they have well defined flow-lines intersection of which implies a physical singularity. Obviously, however, tnis property will be possessed by a much more genera. class of fluids. For these, we define the flow vector as the time-like eigenvector (assumed unique) of the energy-momentum tensor. Then we can replace condition (c) on the nature of the matter by the much weaker condition (e).
(e) If the model is singularity-free, the flow-lines form a smooth time-like congruence with no singular points with
a line through each point of space-time.
Condition (e) will be satisfied automatically if conditions (a) and (c) are.

This proof rests strongly on the assumption of homogeneity which is clearly not satisfied by the physical universe locally though it may hold on a large enough scale. However it would seem to indicate that large scale effects like rotation cannot prevent the singularity.

It is of interest to examine the nature of the singularity in the homogeneous anisotropic models since this is more likely to be representative of the general case than that of the isotropic models. It seems that in general the collapse will be in one direction, 5 that is, the universe will collapse down to a 2-surface. Near the singularity, the volume will be proportional to the time from the singularity irrespective of the precise nature of the matter. It also appears that the nature of the particle horizon is different. There will be a particle horizon in every direction except that in which the collapse is taking place.
4. Singularities in Inhomogeneous Models

Lifshitz and Khalatnikov ${ }^{6}$ claim to have proved that a general solution of the field equations will not have a singularity. Pheir method is to contract a solution with a singularity which they claim is representative of the general solution with a singularity, and then show that it has one fewer arbitrary function than a fully general solution.

Clearly their whole proof rests on whether their solution is fully representative and of that they give no proof. Indeed it would seem that it is not representative since it involves collapse in two directions to a 1-surface whereas in general one would expect collapse in one direction to a 2-surface. In fact their claim has been proved false by Penrose ${ }^{7}$ for the case of a collapsing star using the notion of a 'closed trapped surface'. A similar method will be used to prove the occurrence of singularities in 'open' universe models.
5. 'Open' and 'Closed' Models

The method used by Penrose to prove the occurrence of a physical singularity depends on the existence of a non-compact Cauchy surface. A Cauchy surface will be taken to mean a complete, connected space-like surface that intersects every time-like and null line once and once only. Not all spaces possess a Cauchy surface: examples of those that do not include the plane-wave metrics, ${ }^{8}$ the Godel model, ${ }^{9}$ and N.U.T. space. 10 However none of these have any physical significance. Indeed it would seem reasonable to demand of any physically realistic model that it possess a Cauchy surface. If the Cauchy surface is compact, the model is commonly said to be 'closed'; if non-compact, it is said to
to be 'open'. The surfaces, $t=$ constant, in the RobertsonWalker solutions for normal matter are examples of Cauchy surfaces. If $K=-1$, they have negative curvature and it is frequently stated that they are non-compact. Ihis is not necessarily so: there exist possible topologies for which they are compact. However, the following statements may be made about the topology of the surfaces $t=$ constant.

If the curvature is negative, $\bar{K}=-1$, the universal covering space is non-compact and is diffeomorphic to $\mathrm{E}^{3}$. 11 Any other topology can be obtained by identification of points. Thus any other topology will not be simply connected and, if compact, must have elements of infinite order in the fundamental group. Further if compact, they can have no group of motions. 12

If the curvature is zero, $K=0$, the universal covering space is $\mathrm{B}^{3}$. There are eighteen possible topolofies. 13 If compact they have $a G_{3}$ of motions and Betti numbers, $B_{1}=3$, $B_{2}=3 \cdot 12$

If the curvature is positive, $K=+1$, the universal covering space is $\mathrm{S}^{3}$. Thus all topologies are compact. The Betti numbers are all zero. 12

Since a singularity in the universal covering space implies a singularity in the space covered, Penrose's method is applicable not only to spaces that have a non-compact Cauchy
surface but also to spaces whose universal covering space has a non-compact Cauchy surface. Thus it is applicable to models which, at the present time, are homogeneous and isotropic on a large scale with surfaces of approximate homogeneity which have negative or zero curvature.
6. Mhe Closed Trapped. Surface

Let $\mathrm{r}^{3}$ be a 3-ball of coordinate radius $r$ in a 3 -surface $\mathrm{H}^{3}(\mathrm{t}=$ const.) in a Robertson-Walker metric with $\mathrm{K}=0$ or -1 . Let $q^{2}$ be the outward directed unit normal to $T^{2}$, the boundary of $T^{3}$, in $H^{3}$ and let $V^{a}$ be the past directed unit normal to $\mathrm{H}^{3}$. Consider the outgoing family of null geodesics which intersect $\mathbb{L}^{2}$ orthogonally. At $T_{1}^{2} \rho$, their convergence will be: $\quad \rho=\frac{1}{2}\left(V_{a ; b}+q_{a ; b}\right)\left(S^{a} \rho b+t^{a} t b\right)$ Where sa $t^{a}$ are unit space-like vectors in $H^{3}$ orthosonal to $q^{2}$ and to each other, therefore

$$
\rho=\frac{2}{R}\left[\sqrt{\frac{\mu}{3}-K}-\frac{1}{r} \sqrt{1-K r^{2}}\right]
$$

If $\mu>0$ and $K=0$ or -1 , by taking $r$ large enough, we may make-p negative at $T^{2}$. Therefore, in the language of Penrose, $\mathrm{Tr}^{2}$ is a closed trapped surface. Another way of seeing this is to consider the diagram
in which the flow-lines are drawn at their proper spatial distance from andoserver. They all meet in the singularity at $t=0$. If the past light cone of the observer is drawn on this diagram, it initially diverges from his world-line ( $\rho<0$ ). It reaches a maximum proper radius ( $\rho=0$ ) and then converges again to the singularity $(\rho>0)$. The intersection of the converging light cone and the surface $H^{3}$ gives a closed trapped surface $\mathrm{T}^{2}$. If the red-shift of the quasi-stellar $3 C 9$ is cosmological then it will be beyond the point $\rho=0$ if we are living in a Robertson-walker type universe with normal matter. However, the assumptions of homogeneity and isotropy in the large seem to hold out to the distance of 3 c 9 . Thus there is good reason to believe that our universe does in fact contain a closed trapped surface. It should be pointed out that the possession of a closed trapped surface is a large scale property that does not depend on the exact local metric. Thus a model that had local irregularities, rotation and shear but was similar on a large scale at the present time to a Robertson-Walker model. would have a closed trapped surface.

Following Penrose it will be shown that space-time has a singularity if there is a closed trapped surface and :
(f) $E \geqslant 0$ for any observer with velocity
(g) there is a global time orientation
(h) the universal covering space has a non-compact Cauchy surface $H^{3}$.

## PROOF

Assume space-time is singularity free. Let $\mathrm{F}^{4}$ be the set of points to the past of $H^{3}$ that can be joined by a smooth future directed time-like line to $\mathrm{q}^{2}$ or its interior $T^{3}$. Let $B^{3}$ be the boundary of $F^{4}$. Local considerations show that $B^{3}-r^{3}$ is null where it is non-singular and is generated by the outgoing family of past directed null geodesic segments which have future end-point on $\mathrm{T}^{2}$ and past end-point where or before a singular point of the null geodesic congruence. Since at $T^{2}$, the convergence, $\rho>0$ and since $R_{a b} L^{a} L^{b} \geqslant 0$ by $(f)$, the convergence must become infinite within finite affine distance. Thus $B^{3}-T^{3}$ will be compact being generated by a compact family of compact segments. Hence $B^{3}$ will be compact. Penrose's method is then as follows: approximate $B^{3}$ arbitrarily closely by a smooth space-like surface and project $B^{3}$ onto $H^{3}$ by the normals to this surface. 'his gives a many-one continuous mappins of $B^{3}$ into $H^{3}$. Since $B^{3}$ is compact, its image $B^{3^{*}}$ must be compact. Let $d(Q)$ be the number of points of $B^{3}$ mapped to a point $Q$ of $\mathrm{H}^{3}$. $d(Q)$ will change only at the intersection of caustics of the normals with $H^{3}$. Moreover, by continuity $d(Q)$ can only change by an even number.

But $d\left(T^{3}\right)=1$ since this is the identity and $d\left(H^{3}-B^{3 *}\right)=0$. This is a contradiction, thus the assumption that space-time is non-singular must be false. An alternative proceedure which avoids the slightly questionable step of approximating $B^{3}$ by a space-like surface is possible if we adopt condition (e) on the nature of the matter, then $B^{3}$ may be projected continuously one-to-one onto $H^{3}$ by the flow-lines. this again Ieads to a contradiction since $B^{3}$ is compact and $H^{3}$ is not.
7. Guchyorizons

In the above proof it was necessary to domand that $4^{3}$ be a dauchy surface otherwise the whole of $B^{3}$ micht not heo proje onto $\mathrm{H}^{3}$. wo will dofino a comi-quuchy (s.G.S) as a comploto connocted space-liko supfoce that intersects overy time-lice and null line at most one. usco. $\mathrm{H}^{3}$ will be a cauchy supface for points ion it, is, itwill intersect overy time-like and nul line theugh the points. 8. Singularities in 'Closed' Universes

Mhere is a singulanity in eveny model which satisfies
(a), ( $\quad$ ) and (i).
(i) Hhere exists a compact Cauchy surface $H^{3}$ whose unit normal $V^{a}$ has positive expansion everywhere on $H^{3}$. PROOF

For the proof it is necessary to establish a couple of lemmas. Assume that space-time is singularity-free. The following result is quoted without proof, it may reamily be derived from lemmas proved in reference 11. If $p$ and $q$ are conjugate points along a geodesic $\gamma$ and $x$ is a point on $y$ not in $p q$ then $x$ must have a conjugate point in pq.
in immediate corrollary is that if $q$ is the first point alone $\gamma$ conjugate to $p$ and $y$ is in $p q$ then $y$ has no conjugate points in pq . Also since the result that $x$ has a conjugate point in qq can only depend on the values of $q$ in $p q$, any irrotational geodesic congruence including $m n$
the geodesic $\gamma$ must have a singular point on $\gamma$ in $p q$. Thus if $q$ is a point on $\mathrm{M}^{3}$ and $\gamma$ is the geodesic normal to $m^{3}$ through $q$, then a point conjugate to $q$ alone $\gamma$ cannot occur until after a point conjugate to $M^{3}$.

If $\mathrm{M}^{3}$ is a complete connected space-like surface which intersects every time-like and null line from a point $p$, we may define a function over $\mathrm{M}^{3}$ as the square of the geodesic distance from $p$ which is taken as positive if the geodesic is time-like and negative if the geodesic is space-like. Ye call this the world function $\sigma$ with respect to p. For the closed set of values $\sigma \geqslant 0$, $\sigma$ will be a continuous (in general multi-valued) function over $M^{3}$. A time-like seonesic $\gamma$ from $p$ will be said to be critical if it corresponds to a value of $\sigma$ for which $\sigma_{i \mu} E_{i}^{\mu}=O(i=i, 2,3)$ where $E^{\mu}$ are three independent vectors in $M^{3}$. Clearly a critical geodesic must be orthogonal to $M^{3}$. A geodesic
which is critical will be said to be maximal if it corresponds to a local maximum of

Lemma 1.
A geodesic $\gamma$ cannot be maximal for a smooth $M^{3}$ if there is a point $X$ conjugate to $M^{3}$ but no point conjugate to $q$ on $\gamma$ in $q p$, where $q$ is the intersection of $X$ and $M^{3}$.

Let $f$ and $g$ be the Jacobi fields along $\gamma$ which vanish at $\chi$ and $p$ respectively. They may be written

$$
\underset{m}{f}=\underset{m n}{ } \frac{n}{f}(\mathrm{~s}) \text {, }
$$

Then
n

$$
\begin{aligned}
g & =B(s) g / q \\
m\left(\left.\frac{d}{m} \frac{A_{m n}}{d s}\right|_{q}\right. & \left.-\left.\frac{d B_{m \sim}}{d s}\right|_{q}\right)^{m}
\end{aligned}
$$

must be positive for
any $h$ since if it were negative for any $h$ by taking $a=-b h h$ beyond $q$, it would be possible to have a point $y$ on $\mathrm{mb}^{\mathrm{mb}}$ beyond q conjugate to $X$ before a point conjugate to $P$. If it were zero $X$ would be conjugate to $p$. This shows that the surface at $q$ of constant geodesic distance from $p$ lies nearer to $p$ in every direction than the surface of $q$ of constant geodesic distance from $X$ does. Since $X$ is conjugate to $M^{3}$ the surface at $q$ of constant geodesic distance from $P$ lies closer to in some direction than $M^{3}$ does. Hence $\gamma$ is not maximal.
ust be positive dofinite at $x$. But at

Thuc $\frac{d}{d s}(A-B)$ canot bo positivo deinite at c. wherefore there must be some direction $M$ for which

at q. where m is the unit tangent vector of the conguuger of geodesigs through p. Mhus in the Jirection K the surface of oonstant seotesic distanco from p liog elosex bo p than the sunfaee M Goes. mhenofone of is not maximaz. If $M^{3}$ is compact or if the intersection of all time-like and null lines with $M^{3}$ is compact, $\sigma$ must have a maximum value, thus there must be a geodesic normal to m through p longer than $\gamma$. We use this to prove another lemma. Lemma 2

If $p$ lies to the future (past) on a time-like geodesic o through $q, b e y o n d$ a point $z$ conjugate to $q$, and there exists a compact Cauchy surface $H^{3}$ through $q$, then there must be another time-like geodesic from $p$ to $q$ longer than $\gamma$.

Let $y$ be the last point conjugate to $q$ on $\gamma$ before $p$. Let $x$ be the nearest point to $p$ conjugate to $p$ in pq. Let $r$ be a point in Jx. Let $K^{3}$ be the set of points which have a Iuture (past) directed geodesic of length rq from q. Then

$K^{3}$ will be a space-like hypersurface through $r$. Let $\mathrm{F}^{4}$ be the set of points which have at least one future (past) directed geodesic from $q$ of length greater than $r q$. When the boundary of $F^{4}, J^{3} \subset K^{3}$. Since $p$ is in $F^{4}$ and since every past (future) directed time-like and null line from $p$ intersects $H^{3}$ which is not in $F^{4}$, they must also intersect $J^{3}$. Let I ${ }^{3}$ be the intersection of $J^{3}$ and these lines. Since $\mathrm{H}^{3}$ is compact, $L^{3}$ must be compact. Consider the function $\sigma$ with respect to $p$ over $K^{3}$. Its maximum must lie in the compact region $\mathrm{I}^{3}$. But, by the previous lemma $\gamma$ is not maximal, moreover, local considerations show that a singular point in the surface $\mathrm{J}^{3}$ cannot be a maximum of $\sigma$. Mhus the maximum value of $\sigma$ must occur for a geodesic from $p$ orthogonal to $L^{3}$. This must also be a goedesic from $p$ to $q$ of length greater than $\gamma$.

Using these two lemmas the theoren may be proved. since the future (past) directed normals to $H^{3}$ are converging everywhere on $H^{3}$, there must be a point conjugate to $H^{3}$ a finite distance along each future (past) directed geodesic normal. Let $\beta$ be the maximum of these distances. Let $\rho$ be a point on a future (past) directed geodesic normal at a distance greater than $\beta$. Consider the function $\sigma$ with
respect to p over the compact suriace $\mathrm{H}^{3}$. Iet $A$ be the geodesic from p normal to $H^{3}$ at the point q, wheneo has its maximum. phere must be a point conjugate to $H$ a ang in in But if there is no point conjugate to q along $\lambda$ in $q p$, then $\lambda$ cannot be maximal by the first lemma. If however there is a point conjugate to $q$ along $\lambda$ in $q p$, then there must be a longer geodesic from $q$ to $p$ by the second lemma. Ihus is not the geodesic of maximum length from $H^{3}$ to $p$. Ihis is a contradiction which shows that the oriónal assumption that the space was non-singular must be false.

Ihis proof could also be used to show the occurrence of a singularity in a model with a non-compact Cauchy surface provided that the expansion of its normals was bounded away from zero and provided that the intersection of the Cauchy surface with all the time-like and null lines from a point was compact.
